

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

THE HILLS TELL

A well-known peculiarity of lubricating oil is this:

You will find that with Gargoyle Mobiloil your car will

Chemical or physical tests are often quite misleading.

Two oils of the same gravity may differ in efficiency.

Two oils of the same flash test may be entirely unlike in action.

Oils from widely different bases may be given the same body or viscosity.

Gravity, flash test, body, and viscosity are, therefore, not safe guides to the oil's actual durability or lubricating qualities.

The only real tests of lubricating oil are practical tests.

Hill climbing offers the motorist one good opportunity for practical demonstration. The oil which enables you to climb a hill most easily will be the oil which yields you the greatest horse power.

climb steeper grades on high speed.

If you wish to make a comparative test, pick out a hard hill. See how far up you can go on a high gear with your present oil. Then replace the oil with the correct grade of Gargoyle Mobiloil. Make sure that the operating conditions of your motor are identical in both cases.

The greater distance that Gargoyle Mobiloil will carry you up the hill represents greater actual horse power—resulting from reduced friction and reduced escape of compression and explosion.

You receive this greater efficiency on the level stretches as well as on the hills. It is simply more difficult to measure.

A booklet on lubrication containing our complete chart, which embraces all American makes of cars and the leading foreign makes, will be mailed on request.

The various grades, refined and filtered to remove free carbon, are:

- Gargoyle Mobiloil "A"
- Gargoyle Mobiloil "B"
- Gargoyle Mobiloil "D"
- Gargoyle Mobiloil "E"
- Gargoyle Mobiloil "Arctic"

A grade for each type of motor

They are put up in 1 and 5 gallon sealed cans, in half barrels and barrels. All are branded with the Gargoyle, which is our mark of manufacture. They can be secured from all reliable garages, automobile supply stores and others who supply lubricants.

**Valentine's Automobile
Painting Materials**

Valentine's varnishes are the highest grade vehicle varnishes made—that is, the most brilliant, most easily used, and most durable.

Also, they are of necessity the most expensive; by using them the makers show that they pursue the policy of equipping their cars with the best materials, whatever they cost.

Many other high-grade cars not shown here, through lack of space, are finished with Valentine's materials.

Car owners should ask for Valentine materials when having their cars refinished. Any vehicle painter will use them if specified. Most painters use them regularly.

COES

THE Wrench Supreme

Strength without bulk or clumsiness.

Ease of handling without slipping or bruising.

Perfect balance and right grip

Everything the motorist desires in a wrench is to be found in the "COES" Trade Mark Reg. U.S. Pat. Office AUTOMOBILE MODEL, and you will never know perfect wrench service until you pin your faith to it.

It stands to reason that the 5 per cent. more you pay for a "COES" Trade Mark Reg. U.S. Pat. Office wrench goes for 60 per cent. more quality and service—put this wrench in the tool kit and shop. You will get your money's worth.

The Largest Drop Forge Plant In The Business

TALKING of economizers—take our drop forge plant, which, while it is the largest in the business, is only one small part of our equipment.

Here we operate 40 large steam hammers with a combined striking power of 6,880,000 pounds or 3440 tons.

Also there are over a dozen monster presses and ten Ajax forging machines.

Take one example of the economy such equipment can effect: Overland hammers have an attachment whereby the spring-

seat of a front axle is so perfectly formed (by the hammer blow) that it needs no additional machining.

This operation takes but 30 seconds.

In smaller plants the same work by slow, small factory methods, takes from 30 to 40 minutes.

And this is but one of the hundreds of different economies effected by our huge drop forge equipment.

Now do you see why the Overland costs you 30% less than any other similar car made?

Catalogues free on request. Please address Dept. 52.

The National Motor Truck Display

The Only National Showing of Commercial Cars, Accessories, Parts and Equipment held in America.

The success of the 1913 Display marked New England as the one logical section of the country for such a show.

New England is and will continue to be the Best Commercial Vehicle Market in the country. Every condition is favorable for the use of power driven vehicles and the market has not been scratched.

Will issue, MARCH 10, a special Buyers' Reference Number and it will be mailed in time to reach the hands of owners and prospective purchasers just before the show opens. This edition will reach buyers in this field and all selling interests doing business in these states.

Reo the Fifth

Summer Series
Now \$1,175 Equipped

New-Style Body
Electric Lights
Electric Starter
Electric Horn
One-Rod Control
30 to 35 h. p.
Tires 34x4
Also Roadster

Reo the Fifth appeals to men who are buying a car to keep. Lesser-built cars may run as well at the start. Even for months they may perform about as well as this.

It is the second season, and afterward, when the difference in cars stands out. Then you will know why Mr. Olds insists on his extremes.

A Long-Time Car

Every part in Reo the Fifth is based on 27 years of experience. Legions of men have put Olds-built cars to every possible strain and test. And no man knows better than Mr. Olds the margins of safety needed.

All steel is made to formula, and each lot is analyzed twice. All driving parts are given 50 per cent. over-capacity.

Gears are tested in a crushing machine for 75,000 pounds per tooth. Springs are tested for 100,000 vibrations. Each engine gets five long-continued tests. Each is run for many hours, then taken apart and inspected.

Reo the Fifth has 15 roller bearings. It has 190 drop forgings where steel castings might have flaws. It is built slowly and carefully, with countless tests and inspections. The close-fitting parts are ground over and over.

The extremes we employ add 20 per cent. to the necessary cost of this car. But the result is a car which, for years and years, continues to run like new. An almost trouble-proof car. A

Almost the Last Word In This Class of Car

The Chassis is the final achievement of Mr. R. E. Olds, the dean of all designers. It embodies all of his costly extremes, his care and skill and caution. It marks the utmost in an honest car.

The New Body—this streamline body—is the coming vogue. Europe has adopted it on all her leading cars. And there, where body styles originate, these flowing lines are considered finality.

The Equipment includes all that motorists desire.

The Price this season drops \$220, for reasons stated below. There is no probability that an equal car can ever be built for less.

So this year's Reo the Fifth, in all respects, approaches the limit for this class of car.

safe, staunch car. A car with small cost of upkeep. Men are coming, more and more, to want a car like this.

Classiness

We give equal attention to comfort and beauty. This streamline body follows the lead of the finest cars of the day. No break at the dash, no projecting hinges. The finish is perfection. All possible parts are enameled. The upholstery is of genuine leather, deep and soft. You will hardly find at any price a more luxurious car.

Equipment

All instruments and

gauges are now flush with the dash, and all within reach of the driver. The car comes equipped with the best electric starter we know. All lights are electric, the searchlights have dimming attachment. There is an electric horn, an extra rim, a speedometer, a new tire carrier on the back which holds the tail light and the number.

The windshield is part of the body. It is rain-vision and ventilating.

Then this car alone has our one-rod control. All the gear shifting is done with one small center rod, set out of the way. It is done by moving this rod only three inches in each of four directions.

No levers, side or center—nothing in the driver's way. Both brakes are operated by foot pedals. You never saw such simple control.

Now \$220 Less.

And this year the price drops to \$1,175, with all this complete equipment. Last year's model sold for \$1,395 with electric starter and lights.

There has been some saving in electric equipment, and a lowered cost for tires. But the main saving comes through confining our output to this single chassis for years. All our cost for machinery, tools and jigs has been charged against previous output. From this time on our factory cost is simply the cost of making.

That was what we aimed at three years ago in adopting this final chassis. We have aimed to save you all that changes cost in machinery and equipment. After three years of enormous output this end has been accomplished. Our machinery cost is all wiped out, and we give you the entire saving.

We have dealers in a thousand towns. Ask us for name of nearest one. Also for new catalog.

For Low-Powered High-Speed Engines

there is nothing on the market so effective as the new waterproof, high-tension SPLITDORF "E U 4" MAGNETO. In design and construction it is destined to fill a long felt want in the motoring world as low-powered, high-speed machines can now be equipped with a powerful instrument to give their ignition systems the "kick" they have so sadly needed.

Waterproof and dustproof, the "E U 4" SPLITDORF magneto is made throughout on a principle of strict utility combined with natty appearance and reserve power sufficient for a 30 horsepower motor at high speed.

It is a simple instrument, simple in wiring and easily installed to produce the hottest of hot, fat sparks and guaranteed to give the small high-speed engines a flexible ignition system and a world of reliable "pick-up" power never before attained.

PUBLISHER'S COMMENT.

The Importance of the Boston Show, the biggest and best of them all, has been recognized in recent years by the manufacturers, who have reserved announcement of their newest models for that display. The pleasure car exhibition will be held in Mechanics' building, March 7-14, to be followed, after a lapse of three days, by the only commercial vehicle display of national prominence scheduled for 1914, March 17-21. In every respect this Boston Automobile Show will be the most important event of its character this year.

The Boston Show Numbers of The Automobile Journal will be issued Feb. 27, advance, and March 12, review. For months the editorial staff has been compiling and preparing detailed information concerning the products of the industry which will be presented in these issues in such manner as to make them invaluable as books of reference throughout the coming season. No owner or prospective owner can afford to be without them. They will be retained and referred to constantly, and the information therein can be relied upon as thoroughly dependable. Make certain that

you shall not miss these buyers' references and guides. Order now—direct, or through your news dealer.

Are You a New Owner?—In each issue of The Automobile Journal is a special department (see page 45), devoted particularly to the interests of the man who has purchased his first car. The suggestions contained therein will be found of exceptional value to the novice who desires to secure the utmost in efficiency and economy from his machine. The subjects are treated in simple, non-technical language and are selected with a view to meeting the needs of the greatest number. The Correspondence Department (see page 53) also is available to new owners who may have special problems concerning which they desire advice or assistance. The service is free.

Particular Attention is drawn to the New Accessory Department on page 35, in which are described and illustrated the latest supplies, parts and fittings as soon as they are placed upon the market. Manufacturers are invited to co-operate with the editorial department in making this feature of utmost practical benefit to all.

These Are The Plugs

HERE are the four original Bosch Plugs used in that famous Moline-Knight Test. Official investigation proved them practically perfect after their two weeks, day and night siege.

More than 11,088,000 High Tension Bosch Sparks passed over the electrodes of each plug without a miss and not an adjustment was made during the entire 336-hour run—that IS Plug Service. These Bosch Plugs worked in a compression 33% higher than found in the average engine. Harder service than would be endured in a continuous tour of 14,700 miles at a speed of over 45 m. p. h. Few motorists would subject a plug to a test like this in three years of hard driving, but those who did, would find Bosch Plugs equal to the trial.

You don't chance it when you use Bosch Plugs, because Bosch Plugs are made to be reliable, always.

Be Satisfied. When You Buy Plugs, Buy Bosch Plugs.

\$1⁰⁰ Each, everywhere in U. S.

"Locating the Spark Plug" tells you all you ought to know about plugs—write for a copy, it's free.

TRAFFIC CONDITIONS IN LONDON.

How the Gradual Adoption of Motor Vehicles Has Diverted Traffic from the Railroads to the Streets—Steps That Are Being Taken to Prevent Congestion at Certain Danger Points—Effect Upon Regulation Elsewhere.

WHILE it is a matter of general knowledge that the necessity for traffic regulation has been extended even to the smaller cities of the United States during the past

few years, the reasons for this are, perhaps, not so well understood. The present tendency toward congestion is the result of conditions which did not exist prior to the advent of self-propelled road vehicles, but this statement does not disclose

the entire facts, as will be shown herein. Traffic conditions are most acute in the largest cities—New York and London, for example.

It was in such centres that attention was first directed to the necessity for regulating the use of streets. Herewith are presented two illustrations, which indicate the conditions existing in

the two cities named. One of the views was taken on Regent street, London, and the other at the corner of 41st street and Fifth avenue, New York City.

Because of its position as the largest city in the world, it is not surprising to learn that a consideration

Section of Regent Street, London, England, Indicating Character of Traffic and Method of Handling It.

of this problem was undertaken in London before conditions reached a point in New York, where similar regulation was deemed advisable.

And it may be added that traffic regulation was in vogue in both cities long before the practicability of the automobile was regarded as established.

In studying the illustration it must be borne in mind that in Great Britain, the rule of the road demands that traffic keep to the left, which is exactly the opposite of that which applies in this country. For a number of years it has been found necessary to require that the slow moving vehicles keep next to the curb, permitting the faster traffic to form a moving line nearer the

Traffic on Fifth Avenue, New York City, Between 41st and 43rd Streets.

centre of the street. To some extent this is the plan which police officials have sought to enforce in this country.

Before the advent of automobiles in London, the number of vehicles had increased to a point where it was considered absolutely necessary to adopt this precaution, and it has since been found desirable to designate many streets as one-way thoroughfares, providing four lines of traffic, one for slow moving horse vehicles, one for fast moving horse vehicles, a third for motor trucks and business wagons, and the fourth for the faster moving automobiles. So far as is known no

American city has a similar requirement, although Philadelphia is readily cited as a city having a large number of one-way streets.

Factors of Safety and Efficiency.

But conditions in London have received rather more attention than those in any American city. The London Board of Trade has established a traffic branch which has devoted a large proportion of its time during the past six years to a careful and systematic study of the problem. Traffic regulation is looked upon not only as a safeguard to pedestrians and passengers, but as an efficiency measure, since the lack of congestion has a monetary value to the commercial world.

This traffic branch has taken an annual census each year during the last six, and in addition has accumulated a fund of information covering the whole matter. In connection with the census report for 1913, it is stated that it is safe to assume that 250,000,000 journeys were made during that year on the trunk railway lines within the Metropolis. The local railway companies supply figures which necessitate the addition of 436,492,548 more. The tramways and omnibuses can account for 1,349,109,979. The information takes into consideration only passenger carrying vehicles of a quasi-public character, and shows that practically 60 per cent. of such traffic is by road. Of course, it is impossible to secure such information regarding the number of journeys made by private vehicles, or those made by freight wagons and trucks.

The number of passenger journeys made by road in metropolitan London has almost doubled within the last decade, and the increase in population and the growth of trade have brought, at least, a corresponding increase in the use of the streets by postoffice and railway vans, and by the freight and express handlers generally. In spite of all this additional traffic, however, the road system, with the exception of local additions and improvements, is practically identical with that of a century ago—more especially with reference to the main roads radiating out of London. This statement also would hold true of many other cities, both in this country and abroad.

Effect of Motor Vehicles.

It is conceded in London that it is largely due to the introduction of the more rapidly moving mechanically propelled vehicle that it has been possible for this increased traffic to pass through the streets in their present condition. In other words, even with the normal increase of traffic, it would have been more difficult to avoid conges-

tion had not this increase been of a character of vehicles which helped to solve the problem. This, also, undoubtedly applies to other cities.

But while the introduction of motor vehicles in London has had a tendency to prevent congestion, on the one hand, it has been the means of adding to the possibilities in this direction, on the other, from the fact that there has been a gradual withdrawal of a large amount of traffic from the railways to the roads, as the economy of this type of transportation has been appreciated. Ninety-four per cent. of the passenger vehicles met in London are motor propelled. As yet, only 12 per cent. of the so-called trade vehicles are of this type, but there is a general consensus of opinion as to their practicability and utility, and a gradual extension of their adoption to the exclusion of the horse drawn vehicle is regarded as well assured in all directions.

The data obtained by the investigations of this branch of the London Board of Trade have established facts that will have application in other centres, and will help to explain the necessity for traffic regulation even in the smaller cities in this country. The results also will have a bearing upon future consideration of the problem. Commissions are now at work upon the development of uniform regulations, based upon the systems in vogue in London and elsewhere, which may be adopted generally.

The report accompanying the latest traffic census taken in London is full of interest as setting forth the facts determined. The story is told in the accompanying diagram, which presents a comparison between the census of 1912 and that of 1913, and shows the gradual increase

in the number and volume of motor driven vehicles.

Among the results attained is the determination of many points at which congestion is likely to occur, and where this liability is becoming more accentuated each year. At present, the traffic branch is at work upon a scheme for diverting traffic from these danger points. The report and its accompanying charts, with other information respecting congestion centres, etc., will be laid before the London city councils, in an effort to still further solve the problem of diverting

Results of 1912 and 1913 Census Presented Diagrammatically to Show Relative Increase in Various Types of Vehicles.

the large volume of traffic through the streets in the interests of safety and efficiency.

Jan. 24, fire seriously damaged about 100 imported chassis, for which Moore & Munger of 602 West 52nd street, New York City, was constructing special bodies. This concern is one of the best known body designers and builders in this country, and a large proportion of its business is for owners of imported chassis.

NEW MODELS REVEALED AT CHICAGO.

**Herff-Brooks Company Provides a Surprise with Four and Six-Cylinder Chassis—
Two Non-Poppet Valve Motors Also Make Their Initial Appearance.**

AS WAS expected, several makers of cars and accessories awaited the opening of the Chicago national automobile show before announcing their new models. Of the nine producers of gasoline machines who followed this plan, one was entirely new—or two, if the newly formed Lexington-Howard Company be counted, although the names of the cars manufactured by this concern already were well known. There also were eight makes of electric cars which were not seen in New York, and a number of acces-

poses heretofore. The decorative treatment was such as to represent a conservatory setting, and accompanying illustrations give some idea of the elaborate effect which resulted. This applied to the ground floor of the Coliseum and the armory, while the remainder of the decorations were in harmony with the general scheme.

In attendance and business transacted, the Chicago show set an entirely new record. From the opening night, when the attendance was 15 per cent. larger than at any previous display, the crowds filled the buildings afternoon and evening. There was abundant evidence that the people of the Middle West were quite as much interested in automobiles as those of other sections in which displays have been held since Jan. 1.

New Gasoline Cars.

The one make of gasoline machine which was entirely new was the Herff-Brooks, exhibited by the Herff-Brooks Corporation, Indianapolis, Ind. This was a genuine surprise, for, although the name of this concern appeared on the advance list of exhibitors, it was well known that it was organized to take over the sale of Marathon cars, made by the Marathon Motor Works, Nashville, Tenn. The product of this latter concern also was shown,

and for the first time at a national exhibition this year.

The Herff-Brooks car is produced in two models, a six and a four, each chassis being supplied with either a two-passenger roadster or five-passenger touring body. The motors are the same in general design, the six having bore of four inches and stroke of 4.5, and the four, 4.125-inch bore and five-inch stroke. Both are of the L head type, the four being cast en bloc and the six singly. The clutch is a cone, and the trans-

Looking Down the Main Aisle in the Coliseum, Chicago, Indicating the Elaborate Appearance of the Conservatory Setting.

sories, parts and fittings, including two new non-poppet valve motors. No reference is made to the cyclecar division at this time, this subject being treated elsewhere in this issue.

Just before the opening of the show, which was held Jan. 24-31, it was found necessary to add still another building, the original announcement including the Coliseum, Coliseum Annex and First Regiment armory. The fourth structure was the Greer building, formerly the Wilson, which has been utilized for overflow pur-

mission affords three forward speeds and reverse. The driver is placed at the right, with central control levers.

The other makes which were not seen at New York were the following: Crow Elk-Hart, Crow Motor Car Company, Elkhart, Ind.; Lambert, Buckeye Manufacturing Company, Anderson, Ind.; Westcott, Westcott Motor Car Company, Richmond, Ind.; Pilot, Pilot Motor Sales Company, Richmond, Ind.; McFarlan, McFarlan Motor Car Company, Connersville, Ind., and the Lexington and Howard. None of these is strictly new, except for refinements in design and construction, practically all of which have been announced from time to time in these columns. However, it is worthy of special mention that the McFarlan is fitted with the Gray pneumatic gear shift, the first car to be thus equipped.

New Electric Cars.

The term new is applied to the electric vehicles shown at Chicago solely to distinguish them from the makes seen at New York. As a matter of fact there were no new makes revealed, although the following are to be designated as above: Argo, Broc and Borland, American Electric Car Company; Century, Century Electric Car Company; Chicago, Chicago Electric Car Company; Standard, Standard Electric Car Company; Columbus, New Columbus Buggy Company, and Woods, Woods Electric Vehicle Company. The Borland, Century, Chicago and Woods are made in Chicago; the Broc in Cleveland, O.; the Columbus, in Columbus, O.; Argo in Saginaw, Mich., and the Standard in Detroit.

As with the gasoline models, the changes in design have been presented in these columns, with but one exception, that being the new Columbus colonial brougham, model 1235. This car has a high speed motor driving through a single reduction by means of worm gearing. It carries a 40-cell battery of the 17 lead plate no-wash type. Steering is by means of a side lever, while control is also by horizontal lever above the steering handle. The front seats are of the revolving chair type.

It might also be mentioned that one of the Chicago electrics displayed was a special design built for presentation to Pope Pius X, by a number of Chicago people. It was of the regular models, No. 143, and was distinguished from other cars of this type by the use of the papal coat of arms, embossed in red, on the door panels, and by the special upholstery, also bearing the papal coat of arms.

Non-Poppet Valve Motors.

No new cars fitted with non-poppet valve motors were brought out at Chicago, but two entirely new engines of this type were displayed. One of these, the Charter, invented by J. A. Charter and made by the Charter Single-Sleeve

One of the Side Aisles in the Colliseum Show, Chicago, Presenting Another Detail of the Handsome Decorative Scheme.

Motor Company, Chicago, employs a rotating sleeve valve. The other, the Shaw, made by the Shaw Motor Company, also of Chicago, has a single rotary valve in the cylinder head.

The Charter was shown as a six-cylinder unit. Although described as a single sleeve valve engine, there are in reality two sleeves, one fixed and the other rotating. The fixed sleeve is positioned inside the regulation cylinder casting, next to the piston, and the rotating member is caused to make one revolution between the fixed sleeve and the cylinder walls to every four of the crankshaft. The rotating movement is communicated to the sleeve by a spiral pinion carried on a longi-

tudinal shaft paralleling the crankshaft and driven therefrom.

The fixed sleeve is inserted within the cylinder casting from the top and is anchored thereto by four studs. The top of the sleeve, which is water jacketed, forms the top of the combustion chamber and carries the spark plug. On the sides, suitably positioned, are two openings or ports, one of which serves as the inlet and the other as the exhaust. The rotating sleeve also has two openings, 180 degrees apart, and each of these serves for intake and exhaust purposes. Since the rotating sleeve moves at one-quarter crankshaft speed, one opening uncovers, first the exhaust and then the intake, during one cycle, and the other opening during the succeeding cycle. It would be possible to utilize but one opening in the outer sleeve by arranging to have the sleeve travel at one-half crankshaft speed, but the present method is held to simplify the matter of lubrication.

The Shaw motor was presented as an eight-cylinder unit. The single rotary valve runs along the top of the cylinder casting and is driven from the front by silent chain, completely enclosed in an aluminum casing. The same port is utilized both for intake and exhaust. It is claimed by the designer that the construction makes for a high speed motor, although it may be throttled down to meet any road condition.

The Accessory List.

While there was a large number of accessories, parts and fittings which were not shown in New York, there were few that were entirely new, in the sense that they had never been announced. Readers of The Automobile Journal are familiar with the construction of all devices presented with the possible exception of the Hofbecker-Evans speedlock; the automatic tire rest or motor car jack, made by the Automatic Tire Rest Company, Kansas City, Mo., and the Challon headlight dimmer.

The speedlock consists of a movable disc with a series of figures corresponding to the speed indicator dial on the speedometer. This disc is attached to the top of the speedometer and is controlled by a Yale key. The owner may set the disc at a given figure, and when the speed of the machine has reached that point the ignition is cut off. It is produced by the Hoffecker Company, Boston, Mass.

The tire rest is a jacking device designed to raise the entire car from the floor, the operation being accomplished automatically by driving the car over the jack until the front axle, coming in contact with a coil spring bumper, carries the

rack forward and raises all four wheels from the floor.

The Challon headlight dimmer was exhibited by the Henes Sales Corporation, 179 Washington street, Chicago. It consists of an aluminum disc of less diameter than that of the reflector, so that when it is brought into position in front of the burner, it permits light to pass only around its edges.

SUCCESSFUL TROY EXHIBITION.

Dealers in Three New York Cities Unite in Displaying the Season's Models.

In every respect the fourth annual automobile show held in the state armory at Troy, N. Y., Feb. 2-7, was the largest and best yet seen in that city. As in former years, the dealers in Troy, Albany and Schenectady combined to make the event a success, although it was under the direct auspices of the Troy Automobile Dealers' Association, with Frank M. Baucus as manager, assisted by the officers of the association, as follows: President, Harold G. Hartwell; vice president, Myron J. Adams; secretary, Jesse B. Wilbur, and treasurer, William H. Dennin.

Pleasure cars and trucks were exhibited on the main floor, and accessories in the basement. The general color scheme was tan and turquoise blue, and the bunting thus utilized was partially hidden by a generous use of southern smilax. The list of exhibitors included the following:

Pleasure Cars—Troy Motor Company, Cadillac, Flat; Troy Automobile Exchange, Pierce-Arrow; Bolton-Meyers Auto Truck Company, Haynes; John J. O'Haire, Pilot; Scott D. Nichols, Ford, Reo; Paige-Detroit, Paige; William L. Schupp & Sons, Oakland; Close Bros., Knox; S. B. Ketchum Company, Buick; Franklin Motor Car Company, Franklin; Illum Garage, Maxwell; E. V. Stratton Company, Hudson; Schenectady Welding & Repair Shop, King; L. R. Mack, Packard; Albany Garage Company, Chalmers, Peerless, Simplex, White; George H. Snyder, Stearns-Knight; Wilbur Auto Sales Company, Kissel-Kar, Regal; Payne Automobile Company, Studebaker; Troy Carriage Works, Rauch & Lang electric, Speedwell, K-R-I-T, Case; C. H. Abbott, Overland, Stanley steam; Alrd Motor Company, Stutz, Premier, Apperson, Marmon; Monument Square Garage, Hupmobile, Stevens-Duryea; Herreshoff Motor Sales Company, Herreshoff; Moyer Motor Sales Company, Moyer.

Commercial Vehicles—Troy Automobile Exchange, Pierce-Arrow, Lippard-Stewart; Scott D. Nichols, Reo; William L. Schupp & Sons, Federal; Close Bros., Knox fire apparatus; L. R. Mack, Packard; Albany Garage Company, White; George H. Snyder, Mack, Saurer; Wilbur Auto Sales Company, Kissel-Kar; Payne Automobile Company, Studebaker; C. H. Abbott, Willys Utility.

Accessories—Standard Oil Company of New York, oils; Rensselaer Vulcanizing Works, tires, vulcanizers; Troy Spring Works, springs; J. H. Warren & Co., general line; Charles H. Turner Company, general line; Motor Car Service Works, welding; Post & Lester Company, general line; Cox Brass Manufacturing Company, welding, carbon remover, windshields, starters; Hindsdill Electric Company, electric supplies; Albany Hardware & Iron Company, general line; Alrd Motor Company, welding; Newman E. McHaffy, repair kits.

MANY NEW CARS FOR BOSTON SHOW.

FOR a number of years the annual Boston automobile show, under the direction of Chester I. Campbell, has been recognized in the industry as the biggest and best motor car exhibition of the year. In number of cars on display, in attendance, and in volume and value of sales, it has for several years exceeded that of any other automobile show in the world. It is not surprising, therefore, that the ability of Mr. Campbell as an organizer of successful exhibitions should have extended to other fields.

In the midst of his preparation for the 1914 Boston automobile show, Mr. Campbell recently received a cablegram from the Countess of Aberdeen, Vice Regal Lodge, Dublin, who is president of the Irish Housing & Town Planning Association, urging him to take the management of the civic exhibition to be held in that city during the coming summer and autumn. He replied that he would consider the offer, but would await complete details before announcing his decision.

Two Shows in One.

Concerning the 1914 Boston show: Let it be stated that this really will be held in two sections—Boston being the only city of national prominence which will stage a truck display this year. The pleasure car exhibit will be held in Mechanics' building, under the auspices of the Boston Automobile Dealers' Association, March 7-14. The display of motor trucks and business wagons will follow, in the same building, after a lapse of three days, under the auspices of the Boston Commercial Motor Vehicle Association, March 17-21.

In canvassing the number of vehicles produced in America, and making comparison with those of the last few years, it is found that several concerns which have been represented at previous Boston shows have either gone out of business or have been combined with other companies and the names of the cars have been dropped. Despite this condition, there is every indication that the number of different makes which will be seen this year at Boston will exceed that of any previous show.

Many New Cars Expected.

Already, with practically a month remaining in which entries may be made, over 80 different makes of cars have been listed, and this number does not take into consideration the cyclecars, of whatever class, under the definitions of the Cyclecar Manufacturers' National Association. This number exceeds that of any other year at this time, and it always has been true that sev-

eral machines are entered at the last moment.

The importance of the Boston show has prompted manufacturers to await its opening before making announcement of the latest models. This feature has been particularly true during the past two years, several so-called 1913 models being shown at the 1912 display, and an even larger number of 1914 models at the 1913 exhibit. There is much reason to believe that this practise will be followed more extensively this year, and the present list indicates that there will be on view many cars which have not been exhibited in New England before.

Cyclecars and Accessories.

Of course, this will prove the first real opportunity to study the various cyclecar models in a

show of this character in New England, because the entire cyclecar end of the industry in America has had its inception and growth since the close of the 1913 show season. The accessory department also will be larger than ever before, because, since the Motor & Accessory Manufacturers decided not to make display this year,

the space occupied by members of this association heretofore has been made available to jobbers handling many lines, and therefore the list of individual accessories, parts and fittings has been extended very perceptibly.

The fact that the pleasure car show is to be held first has temporarily overshadowed the importance of the truck display, but Manager Campbell and a staff of special assistants are working on the plans for this exhibit at the same time as the other. Because it will be the only commercial vehicle show of national prominence this year, and because of the importance of New England as a market for motor vehicles of this type, this division of the Boston show will be quite as large as that which will precede it.

Chester I. Campbell, Manager, Boston Automobile Shows.

ROCHESTER SHOW SETS NEW RECORD.

TWO hundred and one automobiles, counting cyclecars; 36 motorcycles, and an equally representative number of accessories, supplies and fittings helped to make up the \$750,000 exhibit, officially termed the sixth annual automobile show of the Rochester Automobile Dealers' Association, in buildings 3, 4 and 5, Exposition park, Rochester, N. Y., Jan. 24-31.

The attendance exceeded all previous records after Thursday evening, a statement intended to mean that those who visited the display Friday and Saturday were over and above all who attended any previous exhibition in that city. The coveted honor of securing the first sale was taken by Thomas J. Northway, who made the sale during the first hour, and there-

Pleasure Cars—F. Porschet, Apperson; Electric Car Sales & Service Company, Broc electric; C. L. Whiting, Buick, Fiat; Mabbett-Bettys Motor Car Company, Cadillac; A. Elliott, Cartercar, Partin-Palmer; Plymouth Garage, Case; Mandery Motor Car Company, Chalmers, Packard, Ohio electric, Standard electric; Strong-Crittenden Company, Chandler, Lozier, Paige; Arthur McNall, Chevrolet, Peerless, Rauch & Lang electric; Shafer-Decker Company, Cole; G. W. Henner, Crow Elk-Hart, Metz, Oldsmobile; F. R. Luescher, Inc., Jeffery, Reo; Jas. Cunningham, Son & Co., Cunningham; Curtis-Pembroke Company, Davis, Winton; Charles E. Sager, Detroit electric; Thomas J. Northway, Ford; Franklin Motor Car Company, Franklin; A. M. Zimbrick, Haynes, Lyons-Knight, Maxwell, Premier; W. M. Klipp, Henderson, Stutz; C. C. Bateman, King; Ball-Washburn Motor Company, KisselKar, Simplex, Vulcan; McKenney & Gilpin, Crescent, K-R-I-T, Oakland; Empire State General Vehicle Company, Locomobile; Paul LeHardy, Marmon; Carthage Auto Company, McFarlan; C. E. Hartson, Hupmobile, National; Overland-Rochester Company, Overland; Almy Auto Company, Palmer-Singer, Pilot; C. F. Oatway, Paterson; Robert Thomson, Pierce-Arrow; A. V. Hart, Regal; John Cunningham-Fordham Company, Speedwell; E. W. Fisher, Stearns-Knight; Peck & Arnold, Stude-

Visitors at the Rochester Show Entered the Exhibit Through Building No. 3, Where Accessories Were Displayed.

after the selling was brisk until the close of the show.

The accompanying illustrations, which present a view in each of the three buildings, indicate the character of the decorations. The same plan was followed, as last year, of causing visitors to enter the show through building No. 3, where the accessory booths were located, and exit after passing through buildings 4 and 5.

The event was under the personal direction of C. A. Simons, as manager, assisted by the following committee: President F. W. Peck, Secretary G. J. Bauer, C. E. Hartson, F. R. Luescher, W. C. Barry, Jr., Paul LeHardy, A. R. McKenney, A. V. Hart, Arthur McNall, C. E. Sager, H. G. Strong and A. M. Zimbrick. The list of exhibitors included the following:

baker; Frank P. Hunt, Velle; Genesee Motor Vehicle Company, Wahl; John Leader & Son Company, Woods electric.

Commercial Vehicles—C. L. Whiting, Buick; Ball-Washburn Motor Company, Chase, KisselKar; F. Porschet, Cleveland, Indiana; John Cunningham-Fordham Company, Federal, Speedwell; Overland-Rochester Company, Garford, Willys Utility; Auto Commercial Company, Horner; G. W. Henner, I. H. C.; Shafer-Decker Company, Kelly; Fitzhugh Electric Garage, L. S. G. electric; Lippard-Stewart Motor Car Company, Lippard-Stewart; W. E. Davidson, Menominee; Mandery Motor Car Company, Packard, Selden, Stewart; C. E. & H. B. Clark Auto Company, Palmer-Moore; Robert Thomson, Pierce-Arrow; W. Ingelow, Service; Sullivan Motor Car Company, Sullivan; Frank P. Hunt, Velle; Vulcan Sales & Service Company, Vulcan.

Cyclecars—E. W. Fisher, LaVigne; W. M. Klipp, Merz. **Motorcycles**—Neff & Malone, Flying Merkel, DeLuxe; Maerchrin, Bloss & Co., Eagle, Henderson, Pope; Ward H. Fisher, Harley-Davidson; E. W. Fisher, R-S; Flynn Bros., Thor; John Kimpson, Yale.

Miscellaneous—A. H. Gabel Company, tops, etc.; Edward Rabe, bodies, tops, fenders; Clifford Company, shock absorbers, tires, rims; Fitzhugh Electric Garage, batteries; Louis Ernst & Sons, Mossberg socket wrenches, Multibestos brake lining, etc.; Rutherford Rubber Company, tires; F. H. Williams & Son, lamps, drip pans, ra-

diators; Rochester Railway & Lighting Company, hydrometers, garage heaters, rectifiers, starters; A. Faber & Co., Golde patent top; E. Q. Williams, ignition devices; Mapes & Burns Manufacturing Company, vulcanizers; Rochester Welding Works, welding outfits; Allen Street Oil Company, Monogram oils; Union Oil Works, oils and pumps; Rochester Rubber Company, supplies; Wagner Dolph Company, side cars; George L. Miner Company, general line.

MANY SALES IN ST. JOSEPH.

Prospects Are Bright for Good Business in District Served by Local Dealers.

The annual show of the automobile dealers in St. Joseph, Mo., was held in the Auditorium, Feb. 4-7, pleasure cars being displayed on the main floor, trucks in the east lobby, and accessories in the right. The city is located in the centre of the wealthiest and most prosperous sections of northwestern Missouri, northeastern Kansas and southeastern Nebraska, and the railroad facilities are such as to make it a large distributing point. The prospect for sales during the coming season is very bright, and this was reflected both by the attendance and sales for the week.

The color scheme was white and green, southern smilax being utilized freely throughout the building. The main floor was arranged to carry out a pergola effect, and the entire interior was illuminated by some

15,000 electric bulbs. Attention was directed to the show each day, by means of a street parade, this being a novelty which worked out with decided satisfaction. The event was under the management of the St. Joseph Automobile Show Association, with the following officers: President, R. R. Calkins; vice president, H. Stubbs; secretary, H. J. Leslie; treasurer, Walter S. McLucas. The following cars were shown:

Overland, Studebaker, Ford, Cadillac, KisselKar, Mitchell, Chandler, Reo, Velie, Buick, Hudson, Stevens-Duryea, Maxwell, Cole, K-R-I-T, Paige, Crescent, Packard, Chalmers, Grant, Premier, Regal, King, Monarch, Dorris, Oakland, Henderson, Enger, Imp cyclecar, Trumbull cyclecar.

According to information from Peru, Ind., E. A. Myers, general manager of the Model Gas Engine Works of that city, is heading a syndicate which has secured control of the Great Western Automobile Company, also of Peru. Milton Kraus, who has been president of the latter concern since the resignation of E. Mack Morris, is said to have withdrawn from the company, and Mr. Myers is to become general manager. The two concerns are understood to have been closely connected, although entirely distinct.

Exhibit of Cars and Decorative Scheme in Building No. 5, Rochester.

MONTREAL SHOW SALES TOTAL \$250,000.

OF THE 42 makes of cars displayed during the first week of the annual Montreal automobile show, held under the auspices of the Automobile Traders' Association in the drill hall, Montreal, Que., Jan. 24-31, 34, or about 80 per cent., were of American manufacture. Of the 14 makes of commercial vehicles shown the second week, Feb. 3-7, 10, or about 70 per cent., were produced in the States. These facts, taken in connection with the story told by the report of exports and imports, issued by the Department of Commerce, which shows Canada to be the American automobile industry's best customer, are of decided interest.

The Montreal show is regarded as a local dealers' exhibition. The Canadian national show is held in Toronto. But Montreal is an important factor in the purchasing end of the in-

met with entire satisfaction, both on the part of the exhibitors and the visitors. The total number of sales for the first week is reported at \$250,000. Among those who made display were the following, it being understood that many of the accessory concerns were represented both weeks:

Pleasure Cars—Automobile Francals, Ltd., Berliet; Albion Motor Company, Arrol-Johnston; Cadillac Motors, Ltd., Cadillac; Comet Motor Company, Packard, Chalmers; Case Company, Case; Dansereau & Co., Stevens-Duryea; Ford Motor Company, Ford; Frigon & Baker, Winton; Fournier & Rodier, McFarlan; Girdwood & Forest, Reo; Gareau Motor Company, Kissel-Kar, Marmon, National, Grant; Grenier-Warrington Company, Pierce-Arrow; Gadbois, Ltd., Palmer-Singer; S. Gagnon & Co., Jeffery; Grothe & Juneau, Franklin; J. L. Gordon & Co., Oldsmobile; N. Herbert & Co., Pullman; Haynes Auto Import Company, Haynes; Keeton Motor Company, Keeton; Legare-Gadbois Company, Hudson, Studebaker; V. Levesque, Abbott-Detroit; Mutual Motor Company, Locomobile, Mercer; Motor Transport Company, Peerless; Major Motor Company, Chandler; McLaughlin-Bulck Company, McLaughlin-Bulck; Oxford Manufacturing Company, Oxford; Pope-Hartford Motor Company, Overland,

Committee in Charge of the Buffalo Automobile Show, including George H. Dreybus, Manager; Charles F. Monroe, Treasurer; John J. Gibson, Secretary; Howard B. Smith, Director; Arthur W. Halle, Director; Ralph E. Brown, President; Edward C. Bull, Director; Gustave C. Miller, Vice President.

dustry in the Dominion. The largest gain in the volume of business done by Canadian dealers during 1913, which was about 75 per cent. over that done in 1912, is credited to that city. The number of high grade limousines and touring cars seen on the streets is such as to occasion decided comment on the part of American visitors, and the business men are fast indicating that they appreciate the economy and efficiency of motor trucks.

This year's event was staged under the management of T. C. Kirby. Two shows were held last year, and in order that all makes of pleasure and commercial vehicles represented in the city might be assembled at the same time, it was decided to divide the exhibition, giving over one week to the former types and a second to trucks and business wagons. The plan seems to have

White; Primm & Co., Simplex; Rousseau Bros., Cole; Russell Motor Company, Russell-Knight; P. A. D. Robert, Jackson; Stockwell Motor Company, Lozier; Spencer Motor Company, Brockville Atlas; Tate Electric Company, Tate electric; Wolseley Motor Company, Wolseley; Weldon Motor Company, Sunbeam, Humber.

Commercial Vehicles—Albion Motor Company, Albion; Automobile Francals, Ltd., Berliet; Canadian Pneumatic Tool Company, Little Giant; Canadian Fairbanks Morse Company, Mack, Lansden electric; Comet Motor Company, Packard; Grenier-Warrington Motor Company, Pierce-Arrow; Jones & Glasgo, Foden steam; Legare-Gadbois Company, Gramm, Stewart; Pope-Hartford Motor Company, White; McLaughlin Carriage Company, McLaughlin; Rousseau Bros., Kelly; Motor Transport Company, Peerless.

Accessories—Bowser Company, tanks; Canada Cycle & Motor Company, general line; Canadian Fairbanks Morse Company, general line; Canadian Consolidated Rubber Company, Ltd., tires; Dunlop Rubber Company, tires; Dominion Chain Company, Weed chains; Express Oil Company, oils and tanks; Franco-American Automobile Company, Ltd., general line; Grenier-Warrington Motor Company, Republic tires; Goodyear Tire Company, Goodyear tires; Gutta Percha & Rubber Company, tires; Gaulois Tire Agency, Gaulois tires; Higgins & Lee, Firestone tires; Independent Tire Company, tires; Imperial Oil Company, oils and tanks; Kelly Tire Company, tires.

TWO DISPLAYS FOR BUFFALO DEALERS.

BUFFALO, N. Y., is one of the few cities of the country which will have an exclusive motor truck show. The pleasure car exhibition of the Buffalo Automobile Dealers' Association was held Feb. 2-7, in the Broadway Auditorium, and this was followed by the commercial display, Feb. 9-14. Judging from the interest manifested by the people of the district for which the city is the commercial centre, as represented by the attendance during the first week, the dealers of Buffalo made no mistake in deciding upon this plan. Many business men are known to be interested in the power wagon, and this exhibition will be the means of directing their particular attention to this end of the industry for one full week.

An accompanying illustration shows the interior of the building during the progress of the pleasure car display, and it will be noted that the main hall is admirably adapted to an exhibition of this character. The trucks and business wagons will occupy the same setting. The splendid success which has resulted wherever automobile shows have been held thus far this year was repeated in Buffalo, and the dealers appear to be warranted in their optimistic view of the outlook for business during 1914. No definite attempt has been made to sum up the sales, but it is stated that these were more numerous than in past years. The accessory exhibit was particularly pleasing and the list of goods represented therein was larger than ever before in Buffalo.

The event was held under the personal management of George H. Dreybus, assisted by the following committee representing the association: President Ralph E. Brown, Vice President Gustave C. Miller, Secretary John J. Gibson, Treasurer Charles F. Monroe and Directors Edward C. Bull, Howard B. Smith and Arthur W. Haile. The following were included among the exhibitors:

Pleasure Cars—Meyer Motor Car Company, Maxwell; A. W. Halle Motor Car Company, Studebaker; Buffalo KisselKar Company, KisselKar; Buick Motor Company, Buick; Buffalo Electric Vehicle Company, Buffalo-Babcock electric; Monroe Motor Car Company, Briscoe, Wahl, Marion; Packard Motor Car Company, Packard; Cole Motor Car Company, Cole; National Motor Car Company, Na-

tional; George Ostendorf, Franklin, Detroit electric; Waverley Electric Sales Company, Waverley electric; Ford Motor Company, Ford; Paige-Buffalo Company, Paige; Poppenberg Motor Car Company, Marathon; Kane-Cadillac Company, Cadillac; Oakland Distributing Company, Oakland; John J. Gibson Company, Mitchell; Oldsmobile Company, Oldsmobile; Ralph E. Brown Motor Car Company, Chandler; J. A. Cramer, Marmon, Jeffery, Regal; A. L. Dixon, Velle; Overland-Buffalo Company, Overland; Buffalo Hudson Sales Company, Hudson; Mason B. Hatch, Inc., Chalmers; J. I. Case Threshing Machine Company, Case; Louis Engel, Jr., Cartercar, Partin-Palmer; Harry A. Hall, Detroit; Pierce-Arrow Sales Company, Pierce-Arrow.

Accessories—Chas. E. Miller, general line; Klepfer Bros., Joseph Strauss & Sons, Hurd & Landsheft, Wayne Oil Tank & Pump Company, Iroquois Rubber Company, Keystone Lubricant Company, John W. Frey, Standard Limousine Top Company, American Kusion Kar Tire Company, Clifford Company, Kendall Refining Company, F. A. Lobee, Jaynes Auto Supply Company, Pyrene Manufacturing Company, Miller Sales Company, Great Western Oil Company, Indian Refining Company, Niagara Metal Weather Strip Company.

General View in the Broadway Auditorium, Buffalo, N. Y., During the Pleasure Car Show.

One of the meetings of special interest held during the recent Chicago automobile show was a conference between the licensees under the Knight motor patents, and the holder of those patents. There does not appear to have been any attempt to form an organization, but the following concerns were represented: F. B. Stearns Company, Cleveland, O.; Moline Automobile Company, East Moline, Ill.; Lyons-Atlas Company, Indianapolis, Ind.; Willys-Overland Company, Toledo, O., and the Knight & Kilbourne Patents Company. Charles Y. Knight, inventor of the engine, gave a talk, in which he stated as his opinion that more progress had been made during the past year in the development and commercial growth of the sleeve valve motor than had occurred during the previous five years.

VANDERBILT AND GRAND PRIZE RACES.

ENTRIES for the Vanderbilt Cup and Grand Prize races closed at midnight, Feb. 9, and any blanks placed in the mail previous to that hour will be considered. From present indications, however, there will be 11 contestants in the former event and 12 in the latter. The race for the Vanderbilt Cup will be held over the Santa Monica road course, Feb. 21, and that for the Grand Prize, Feb. 23. The entry list reads as follows at present:

Vanderbilt and Grand Prize.

Car	Driver	Entrant
Stutz	Anderson	Stutz Motor Car Company.
Delage	Toft	Leotia K. Northam, Inc.
Mercer	Wishart	Mercer Automobile Company.
Mercer	Pullen	Mercer Automobile Company.
Stutz	Cooper	Walter M. Brown Company.
Isotta	Grant	W. Zeigler.
Simplex	Leotia K. Northam, Inc.
Mercer	Oldfield	George R. Bentel.
Sunbeam	Marquis	W. Zeigler.
Mercedes	De Palma	E. J. Schroeder.
Mercedes	Pilette	E. C. Patterson.

Grand Prize Alone.

Flat, Tetzlaff, Savage Tire Company.

It will be noted, from examination of the above list, that these two events present an entirely new situation in American automobile racing circles, since this is the first time that a woman has been permitted to make entry. The rules of the contest board of the American Automobile Association prohibit a woman from taking part in an event of this character, either as driver, mechanic or entrant. Mrs. Northam appears to have found a way to avoid the prohibition of this rule by getting herself incorporated, and it is understood that she intends to enter cars in all the long distance races held during 1914, including the 500-mile race on the Indianapolis motor speedway.

It is also worthy of note that this is the first time that these two great American road racing classics have been held on the Pacific Coast. The Vanderbilt Cup race was originated in 1904, and for a number of years was held over a course on Long Island. In 1911, it was shifted to Savannah, Ga., where it was held in conjunction with the Grand Prize, which was originated in 1908 and which had been held over the Savannah course twice before. In 1912, both races were held near Milwaukee, Wis. There was no Vanderbilt Cup event in 1907 or 1913, and the Grand Prize has been held only in 1908, 1910, 1911 and 1912.

Thus it will be seen that the forthcoming Vanderbilt Cup event will be the ninth for this award, and the Grand Prize race will be the fifth

of that name. The results in the previous contests are set forth in an accompanying table.

The races this year will be started promptly at 10 in the morning. Fred J. Wagner will act as starter, and the other officials will be as follows: Referee, George Purdy Bullard, attorney-general for Arizona, who founded the annual desert classic, known as the Los Angeles-Phoenix road race; judges, A. B. Daniels of Los Angeles, C. H. Cobb of Fresno, and John F. McLain of San Francisco; chief scorer, E. W. Leslie of Los Angeles; technical committee, W. E. Bush, C. J. Smith and F. W. Young, all of Los Angeles.

The course is the same as that over which the annual Santa Monica road races have been held in recent years, and is regarded as one of the fastest in the world. Harvey Herrick secured a world's road record over it with a National car in 1911, and the present world's road record, held by Teddy Tetzlaff in a Fiat at 78.5 miles an hour, was made in the Santa Monica road race of May 4, 1912.

Each lap is 8.401 miles in circumference. The Vanderbilt Cup race will cover the course 35 times, making a total distance of 294.035 miles, while the Grand Prize will be for 48 laps, or 403.248 miles.

In connection with the holding of these races, the Bosch Magneto Company, New York City, for which the Motor Parts Company, Boston, Mass., is New England representative, following a practise which it originated some years ago, has set aside \$1900, to be awarded as special prizes. In case the car is fitted with a Bosch magneto, the winner in the Grand Prize will receive \$500, the driver in second place \$150 and the driver in third place \$100. The same condition applies in the Vanderbilt Cup race, with the exception that the special prizes are: First, \$300; second, \$150; third, \$100. In addition, since the equipment on some cars is not fully Bosch, but Bosch plugs are used, a second set of prizes has been set aside, providing for an award of \$100 to the

Previous Vanderbilt Cup Winners.

Year	Car	Driver	MPH
1904	Panhard	Heath	52.02
1905	Darracq	Hemery	61.50
1906	Darracq	Wagner	63.00
1908	Locomobile	Robertson	64.40
1909	Alco	Grant	62.08
1910	Alco	Grant	65.02
1911	Lozier	Mulford	74.07
1912	Mercedes	De Palma	68.82

Previous Grand Prize Winners.

Year	Car	Driver	MPH
1908	Flat	Wagner	65.04
1910	Benz	Bruce-Brown	70.55
1911	Flat	Bruce-Brown	74.45
1912	Flat	Bragg	68.40

driver in first, second or third place in either race, with car thus equipped. Another interesting point is that Bosch equipment has so invariably been used by winners of all big and important races, that the money is offered by the Bosch Magneto Company with a feeling that it actually will be won.

SHOW IN PORTLAND, ORE.

Elaborate Decorative Scheme Provides Setting for the 100 Machines on Exhibition.

About 100 machines were displayed at the fifth annual show of the Portland Automobile Trade Association, in Portland, Ore., Jan. 27-31. The event was under the management of Capt. E. H. Gray, president of the association, and was a decided success in every respect.

The general color scheme was green and white, but the side walls were entirely hidden by a painting designed to represent a road leading out of the city, past the Automobile Club, along the Sandy river, and to Crater lake, Mt. Hood and the Three Sisters, with St. Helens, Mt. Rainier and the Columbia river in the distance.

The second floor was given over to accessories, and this section was even more complete than in past years. No attempt was made to decorate the truck section, in the basement.

FINE DISPLAY IN PORTLAND, ME.

Second Annual Event for Dealers in That City Opens in City Auditorium.

The second annual show of the Portland Automobile Dealers' Association, Portland, Me., was opened in the City Auditorium, Jan. 9, for the remainder of the week. The number of exhibitors was such that only cars and trucks were displayed on the main floor, the accessory booths being located in the lobby. The list of exhibitors includes the following:

Vehicles—Portland Chevrolet Company, Chevrolet; Maine Motor Car Company, Peerless, Stevens-Duryea, Paige, Chalmers; Miles B. Mank Motor Car Company, Cadillac; Arthur F. Talbot, American; Franklin Motor Car Company, Franklin; Gilson Auto Company, Mitchell, Studebaker; Portland Company, Knox, Cole; F. A. Nickerson Company, Pierce-Arrow; Spear Auto Company, Ford, Maxwell; W. B. Thombs, Buick; Stoughton-Folkins Company, Oakland; Sanborn Motor Company, Speedwell; E. E. Wentworth, Overland; Payson Motor Truck Company, GMC trucks; Hollander Motor Company, Cartecar.

Accessories—York & Boothby, electrical supplies; L. W. Cleveland Company, general line; T. L. Merrill Company, general line; Standard Oil Company, lubricants; Wiley & Smith, polishes; Maine Motor Car Company, general line; Talbot, Brooks & Ayer, supplies; Standard Vulcanizing Company, vulcanizers; Maine Auto Tire & Supply Company, tires, general line.

RESULTS AT MINNEAPOLIS.

Dealers Are Very Optimistic at Close of Seventh Annual Display.

Attendance at the seventh annual show of the Minneapolis Automobile Trade Association, which was held in the state armory, Minneapolis, Minn., Jan. 31-Feb. 7, was larger than ever before, and the number of sales was large in proportion. There was every evidence to indicate that the dealers in that city are very optimistic as to the possibilities of the 1914 season.

The show occupied 75,000 square feet of floor space, or 5000 feet more than last year. Forty-one dealers were represented, three of these showing electric cars, and four cyclecars. There were also 17 makes of trucks on display.

MOTORCYCLE PLANT SOLD.

Bosch Magneto Company Buys Brockton Factory and Disposes of It Again.

The property of the American Motor Company, Brockton, Mass., which was sold under mortgagee's sale Jan. 20, was purchased by the Bosch Magneto Company, New York City, and immediately transferred to G. M. Green and William T. Marsh, the latter the treasurer of the first named concern. It is understood that steps are under way for a reorganization of the company. Mr. Marsh is authority for the statement that the name of the new company will be the Sterling Manufacturing Company.

Elbert Hubbard has issued, from the Roycrofters press, East Aurora, N. Y., a handsome little brochure, entitled, "Opportunity, Being a Little Journey to the Republic Clubhouse". The text gives an interesting account of the writer's recent visit to the employees' clubhouse, recently opened by the Republic Rubber Company, Youngstown, O., an illustration and brief description of which was presented in the Jan. 25 issue of The Automobile Journal.

The Keystone Vehicle Company, Reading, Penn., has elected the following directors for the ensuing year: Robert E. Brooke, George Brooke, Edward C. Nolan, J. Bennett Nolan, John L. Coxe, F. Burmeister, H. John Herb and H. P. Burmeister. The directors have chosen the following officers: President, H. J. Herb; treasurer, J. E. Ely; secretary and general manager, H. P. Burmeister.

WILLYS-KNIGHT HAS MANY REFINEMENTS.

AMONG the latest entrants in the sleeve valve class is the Willys-Knight car, made in a five-passenger touring car and roadster, which was exhibited for the first time at the New York show. When it was announced that the Willys-Overland Company had taken over the Edwards-Knight, and would manufacture the machine at the Garford plant at Elyria, O., a number of important changes were anticipated by those cognizant of the progressiveness of the Willys-Overland Company. The new car still retains a number of interesting Edwards-Knight features such as the oil submerged worm gear rear axle, Lanchester cantilever rear spring suspension and wire wheels.

The Willys-Knight motor incorporates the

drop forging of an alloy steel, and is hollow with the exception of the cheeks. It rotates in five large babbitt lined bronze bearings. The connecting rods are of the tubular section, drop forged.

The valve sleeve eccentric shaft is actuated by a silent chain, and a similar member drives an auxiliary shaft on the right hand side of the motor, operating a very large centrifugal water pump, magneto and a gear for driving the power tire pump, which is mounted on a bracket just above the pump. Use of the tire pump is obtained by meshing a gear with a similar member located on the shaft between the magneto and water pump.

The magneto coupling is not only well de-

Five-Passenger Willys-Knight Touring Car, a Handsome Machine Equipped with Latest Design of Knight Sleeve Valve Motor.

latest improvements made in the Knight engine and is produced at the Elyria plant. The cylinders are cast in pairs and, as in all Knight engines, the heads are constructed separately and are water jacketed. The water jackets of the cylinders extend the full length of the bores. The cylinder dimensions are four by 5.5 inches and the S. A. E. rating of the horsepower is 25.6, but it is stated that the motor develops 40-45 at normal speed. One reason advanced for the power developed is that the combustion chamber formed by the concave cylinder head and piston, is as nearly spherical as possible on a practical engine. It is also pointed out that much of the heat units lost through the water jackets is turned into useful energy in the Willys-Knight motor.

The crankcase is divided, four arms integral with the upper half providing a four-point suspension of the power plant. The crankshaft is a

signed, but makes timing a simple matter. Ignition is by the latest type Simms magneto, providing a hot spark at low motor speeds. A noticeable feature of the ignition system is that the switch is eliminated, the spark lever being fully retarded when it is desired to stop the operation of the motor. Provision is made, however, for locking the ignition circuit. Carburetion is by a specially designed Stromberg.

The lubrication system is simple, and the supply of oil is proportioned to the speed of the motor. This is obtained automatically, and by a connection with the throttle. The pump is of the plunger type, located in the crankcase, and a perfect distribution of the lubricant is secured through grooves cut around both sleeves from which the oil is distributed and through which the excess is returned to the reservoir. The capacity of the oil container is three gallons.

The clutch is a leather faced cone, 15 inches in diameter and having a 2.25-inch face. Easy engagement is assured by the use of eight flat

Right Hand Side of Willys-Knight Motor, Showing Method of Driving, Water Pump, Magneto and Power Tire Pump.

springs. Between the clutch and gearset are two universal joints, the rear being a leather construction, which not only allows for easy displacement, but reduces stresses created by a sudden application of power. The gearset provides four forward speeds, with a direct drive on the third. Between the gearset and the rear axle are two universal joints, reducing vibration to a minimum.

The rear axle is of the worm type, with the worm gear submerged in oil. The worm is located underneath the gear, and the road clearance is ample to meet all conditions of service. The housing is of pressed steel, with worm and wheel supported on an under cover, and a large inspection plate permits of easy access. The construction is reinforced substantially by two ample sized truss rods. Annular ball bearings are utilized throughout the axle, and the driving shafts are of the full floating type, of generous dimensions and of a high grade material.

The rear construction is a departure from conventional lines, as will be noted by an accompanying illustration. In the first place, the rear springs are of the floating type, the Lanchester cantilever design, and are attached directly to the rear axle, but slide over and bear upon a roller which permits of a free backward and forward movement. Provision is made, however, for excessive action or accident to the radius

rods. The spring may be described as an inverted semi-elliptic, fulcrumed at its centre to the frame and shackled at front. Easy riding qualities and an absence of vibration are qualities of the construction emphasized. Provision is made for lubrication.

The radius rods are so attached as to bring them in the same plane as the propellor shaft, and a torque arm is also provided, being connected at its forward end by a spring link with a ball and socket joint. The front springs are semi-elliptic, 38.5 by 2.25 inches. The rear members are 52 inches long, 2.5 wide and have nine leaves.

Two sets of brakes are provided, both on the rear wheels. They are of the internal expanding design, the service being on 16-inch and the emergency on 12-inch drums, both with two-inch face. The frame is of pressed channel section steel, 4.0625 inches deep and 3.25 wide, hot riveted, and provided with a double drop. The various units are supported without sub-frames. The cellular type of radiator is so mounted that it is not affected by road shocks, etc. Its capacity is ample to meet all conditions of service.

The driver is placed at the left, with the gear shifting lever operating through a ball and socket joint in the gearset housing. The emergency brake lever is just to the right of the speed lever, with the locking quadrant below its fulcrum and to the right of the transmission case cover, where the pull rod is attached. The Warner speedometer is driven by a gear at the rear of transmission, the driving member being secured to a section of the universal joint. The steering gear is of the worm and gear type, enclosed in a grease tight case, and eccentric bushings are fitted to take up wear. The steering column is set at a comfortable angle and is surmounted by an 18-inch wheel. Spark and throttle levers are mount-

Chassis of Willys-Knight, Having a Low Centre of Gravity and Incorporating Many Refinements.

ed on the wheel. Usual accelerator is provided.

The wheels are of the standard demountable wire type with quick detachable rims, and the

tire size is 36 by 4.5 inches all around. The wheelbase is 120 inches and the tread standard, 56. One of the features is the short turning ra-

Worm Driven Rear Axle of Willys-Knight, Showing Substantial Proportions and Torque Arm.

dus, it being stated that the car can be turned in 18 feet.

The electric motor starting and lighting system is the U. S. L., which is built into the flywheel of the motor. The unit is a motor-generator in that it functions as a motor for starting and automatically operates as a dynamo for lighting or charging the battery. A feature of the system is the incorporation of a manually operated switch by means of which the driver may cut out the dynamo, a practise in vogue abroad. This prevents any possibility of overcharging the battery and permits of locking the circuit when the car is left unattended.

The body is an all-steel construction, placed over a wooden frame, with rolled moldings. The doors are equipped with lever latches and case hardened concealed hinges. The upholstery is extra deep, being of the finest hand buffed leather over special coiled springs and imported hair. The front cushions are adjustable to enable the driver to operate the pedals easily.

All trimmings are nickel plated. The floor and toeboard of the driver's compartment are covered with linoleum, while carpet is utilized in the tonneau. Ample space for the carrying of goggles, veils, etc., is provided by large pockets in the doors.

The usual foot and robe rails are included in the equipment, and the tool boxes, which are located under the running boards, are extra long and capable of storing a complete touring equipment. A one-man top is standard equipment, and a storm apron and side curtains are included. The one-piece windshield is a special design, and provision is made for ventilating the forward compartment. The power tire pump is a four-cylinder unit. The balance of the equipment includes electric horn, extra wire wheel and carrier, Truffault-Hartford shock absorbers in front, jack, tools, etc.

NEW BUILDING IS COMPLETED.

Teetor-Hartley Motor Company Also Takes Over Business of Older Concern.

Announcement is made from Hagerstown, Ind., that the new factory building of the Teetor-Hartley Motor Company is completed and preparations are being made for its immediate occupancy. The structure is three stories high, 144 feet long and 66 feet wide, and is of brick.

The management of the concern remains unchanged, the following officers having been re-elected at the first of the year: President, J. H. Teetor; vice president, H. W. Keagy; secretary, C. N. Teetor; treasurer, W. E. Immel. It is stated, however, that all business heretofore conducted under the name of the Light Inspection Car Company, will be carried on by this concern in the future.

The Light Inspection Car Company was organized in 1895 for the purpose of building light inspection cars for use on railroads. A few years later a stationary gas engine became one of its productions. In 1898, when the automobile gave promise of being a commercial factor, C. N. Teetor invented the well known Teetor T head motor, and very soon the demand for this engine reached such proportions that it was necessary to dispose of the stationary engine business and devote greater attention to the Teetor motor.

The first annual automobile show in Easton, Penn., will be held in the state armory, Feb. 18-21, under the auspices of Co. I, 13th Infantry, N. G. P., and the personal direction of H. W. Lasher as manager. The show has been advertised extensively throughout the district of which Easton

Langhester Cantilever Rear Springs Employed on the Willys-Knight.

is the centre, and special effort will be made to attract farmers on Thursday of show week. One evening will be designated as Society Night.

GENERAL NEWS OF THE INDUSTRY.

Licensees Under Canfield Spark Plug Patent Form Association---Company Organized to Produce Kerosene Burning Cars---Changes in Personnel, Etc.

SEVENTEEN of the 31 spark plug manufacturers licensed under the Canfield patent, held by the A. R. Mosler Company, Mount Vernon, N. Y., formed the Association of Spark Plug Manufacturers in Chicago during the progress of the automobile show in that city. The new association decided on a definite policy, which is represented by the following:

To foster the interests of those engaged in the trade or business of manufacturing spark plugs or parts thereof.

To procure uniformity and certainty in the customs and usages of such trade or business.

To reform abuses relative to such trade or business. To secure freedom of its members from unjust or unlawful exactions.

To diffuse accurate and reliable information as to the standing of merchants and others dealing with the members, and as to the condition and development of the trade or business in which the members are engaged in the United States.

To advocate the enactment of just and equitable laws affecting the members.

To settle differences between the members.

To promote a more enlarged and friendly intercourse among the members.

Only two officers appear to have been elected at this meeting, these being J. W. Fisher of the Silvox Company, New York City, as secretary, and A. R. Mosler as treasurer. A committee, consisting of R. E. Mills, Rajah Company; R. A. Stranahan, Champion Spark Plug Company; Albert Champion, Champion Ignition Company; Emil Grossman, Emil Grossman Manufacturing Company, and E. M. Benford, Benford Manufacturing Company, was appointed to investigate and report on all matters relating to the spark plug industry and to bring to the notice of the association all infringers of the Canfield patent, those who are conducting their business on a false basis, or, in other words, misrepresenting their products, and those who are in any way harmful to either the industry or the consumer's welfare. This committee, of which Mr. Benford is chairman, also has power to set the date for the annual meeting in January.

WIRE WHEEL ACTION.

Rudge-Whitworth Company Said to Be Co-Operating with Houk Concern.

Advices from Buffalo, N. Y., said to be based on cables from Liverpool, England, indicate that Rudge-Whitworth, Ltd., of England is co-oper-

ating with the Houk Manufacturing Company of Buffalo, in adjusting the differences existing between the latter concern and the Standard Roller Bearing Company of Philadelphia, which recently brought suit, claiming to be the sole American licensee for the manufacture of Rudge-Whitworth wire wheels or wire wheels embodying features of these.

George W. Houk, president of the Houk Company, sailed from Liverpool, Feb. 1, having been to the Rudge-Whitworth factory for a conference with the parent company in connection with the Houk wire wheel, produced by his concern, and in which there are said to be incorporated constructional features covered by the Rudge-Whitworth patents. It is understood that, as a result of this conference, Mr. Houk cabled his concern to prepare for enlarged manufacturing facilities.

TO BUILD KEROSENE CARS.

Richard Automobile Manufacturing Company Is Organized in Cleveland, O.

Francois Richard, a French engineer, is said to have interested American capital in the production of a car which will be fitted with a motor and carburetor designed especially to utilize kerosene. The factory is to be located in Cleveland, O., according to information from that city.

The Richard Automobile Manufacturing Company has been organized in Cleveland with capital of \$250,000. It is understood that F. M. Brady of the Cleveland Brick & Clay Company, and G. C. Gordon of the Park Drop Forging Company are associated with Richard in the enterprise.

An experimental car is said to be under construction in New York City, although many of the parts are being made in Cleveland from designs furnished by Richard. He claims that with an engine of the four-cylinder, four-cycle type, having a horsepower of 90, he will be able to drive 30 miles to a gallon of kerosene. According to the public announcement, the car will be made in one chassis and body design, this being a seven-passenger touring car with 128-inch wheelbase.

GOODRICH'S ANNUAL REPORT.**Statement Made Public at Close of Year Shows Profits of \$2,600,000.**

According to a statement made public by the B. F. Goodrich Company, Akron, O., maker of Goodrich tires, the profits for the year 1913, after deducting proper allowances for maintenance, depreciation and other items, were approximately \$2,600,000. This result added to the surplus carried over from Dec. 31, 1912, shows an undivided surplus of \$700,000, after paying a full year's dividends of preferred stock and one per cent. on common stock.

The financial position of the company is stated to have been materially strengthened during the year. The quick assets, as of Dec. 31, 1913, were approximately \$20,000,000, against current liabilities of \$4,000,000, so that the quick assets are now five times the current liabilities. At the time of the last annual report the ratio was 3:1.

TO PRODUCE R-C-H CARS.**C. P. Seider Will Continue Manufacture Under Old Firm Name.**

C. P. Seider of Detroit has taken over a large portion of the assets of the R-C-H Corporation of that city, the entire property of which was purchased recently at receiver's sale by the Todd, Frank, Friedberg Company. It is announced that a new concern will be formed with the old name, and that the manufacture of R-C-H cars will be continued by it.

A. H. Collins, a former distributor of these machines, is associated with Seider in the deal, although it would appear that for the present the holdings are in the name of the latter. These include practically everything pertaining to the assembly of cars, including buildings and real estate, but not the foundry, machine shop or forging plant.

DAYTON TRUCK COMPANY.**Assets Acquired by Recently Incorporated Durable Dayton Company.**

Articles of incorporation have been filed with the secretary of state in Columbus, O., for the Durable Dayton Company of Dayton, O., which is to succeed the Dayton Auto Truck Company, recently petitioned into bankruptcy. The property was sold at trustee's sale to Attorney H. P.

Williamson, who is understood to have represented the new concern.

The factory is in operation, and, according to an announcement by Mr. Williamson, will continue, although the plans of the new company have not been made public as yet.

MOSKOVICS WITH MARMON.**Resigns as Secretary of Jones Electric Company to Help Sell Well Known Car.**

Frederick E. Moskovics, secretary and sales manager of the Jones Electric Company, Chicago, has resigned to join the sales organization of the Nordyke & Marmon Company, Indianapolis, Ind., maker of the Marmon car. He is one of the best known men in the industry and his acquisition by the Indianapolis concern is one which merits congratulations for both.

Mr. Moskovics is another graduate from the bicycle industry, where he early made a name for himself as a salesman of exceptional ability. His first work in the automobile field was in connection with the introduction of a foreign tire to this country. Then he entered the parts business in New York City, selling practically everything that can be used in motor car construction.

Later he served an apprenticeship with Gottlieb Daimler at the latter's German factory. Then he designed and built the Yellow taxicab in New York City. Next he organized the Motor Pacing Association of New York, helped to build the Los Angeles motordrome and assisted in the organization of the Society of Automobile Engineers. Perhaps he is best known as manager of the sales department of the Remy Electric Company, a position he relinquished to become secretary of the Jones Company.

ANGLADA ORGANIZES COMPANY.**Liberty Cyclecar Will Be Produced in New York by Liberty Motor Company.**

Final details have been completed for the production of the Liberty cyclecar, designed by Joseph Anglada, a well known member of the Society of Automobile Engineers. The concern will be known as the Liberty Motor Company, and it is stated that a suitable factory site has been secured in New York City and that manufacturing will commence shortly. The officers of the company are: President, Joseph Anglada; secretary, C. S. Ackley of the McKiernan Terry Drill Company, and treasurer, A. W. Drake, formerly head of the Harward Electric Company.

PORTER SUCCEEDS HOUCK.**Will Direct the Sales Policy for Producer of Car-Nation and Keeton Cars.**

Following closely upon the announcement that the American Voiturette Company, Detroit, would take over the manufacture and sale of Keeton cars, in addition to its Car-Nation small car line, comes the statement that W. G. Houck, who has held the position of sales manager since the organization of the company early last year, has resigned. His resignation took effect Jan. 21, and, as yet, his plans for the future have not been made public.

Mr. Houck has been succeeded by Joseph D. Porter, one of the pioneer salesmen in the industry. He has been associated with the Garford Company of Elyria, O., for the past seven years, and during the last two years of that connection he was sales manager. In securing Mr. Porter's services, General Manager H. H. Newsom of the American Voiturette Company has acquired a man of wide experience and one who has personal acquaintance with a large number of dealers throughout the country.

WILLYS IN CANADA.**New Concern Will Take Over and Operate Old Schacht Plant in Hamilton.**

Announcement is made of the organization of the Willys-Overland Company of Canada, Ltd., with John N. Willys as president. The new concern will locate in Hamilton, Ont., where it has acquired the plant formerly operated by the Schacht Motor Company. The other officials of the concern will be announced later.

The company will manufacture pleasure cars and business wagons, presumably bearing the same names as those produced by the Willys-Overland Company and its subsidiaries in this country. The capital is placed at \$500,000.

STEWART-WARNER STATEMENT.**Speedometer Concern Makes Public Financial Condition at Close of Year.**

In a statement of its financial condition at the close of business, Dec. 31, 1913, the Stewart-Warner Speedometer Corporation of Chicago discloses that the earnings for the year, after deducting charges and all allowances, were \$1,145,132, and the surplus \$573,027. The net earnings

are equal to seven per cent. on the \$1,000,000 preferred stock and 10.5 per cent. on the \$10,000,000 common outstanding.

The consolidation was formed in 1912, and the above net earnings are compared with those of previous years as follows: 1913, \$1,145,132; 1912, \$917,373; 1911, \$846,250; 1910, \$842,807; 1909, \$596,843. Except for 1913, these figures are taken from the reports of the companies entering into the consolidation.

PELLETIER WITH LOZIER.**Will Act as Advertising Counsel While Still Serving Maxwell Motor Company.**

One of the interesting announcements of the Chicago show week was that made by President Joseph M. Gilbert of the Lozier Motor Company, Detroit, in which it was stated that E. LeRoy Pelletier had been engaged as advertising counsel for that concern. Mr. Pelletier already holds the same position with the Maxwell Motor Company of that city, and it is explained that he will continue that connection while acting for the Lozier concern.

The two men have been friends since the inception of the automobile industry, and the same thing is true with respect to Paul Smith, sales manager for the Lozier, who served with Mr. Pelletier in the old E-M-F Company. The last named is one of the best known advertising men in the country, in this field, and the Lozier company is to be congratulated in securing his services.

COMPLETES REORGANIZATION.**New Columbus Buggy Company Starts Business with Capital of \$500,000.**

The New Columbus Buggy Company was incorporated in Columbus, O., Jan. 24, with capital of \$500,000, all common stock. It is understood that this stock is held by about 85 per cent. of the creditors of the former concern, who have been operating the plant for the past eight months. It is further stated that the claims against the old company amounted to \$464,000, which will be taken up, leaving a balance of \$36,000 for organization expenses.

The officers of the new company are: President, George W. Lattimer; vice president, E. R. Sharp; secretary, D. N. Postlewaite; treasurer, George W. Bright. The board of directors is composed of the following: O. A. Miller, George

W. Bright, George W. Lattimer, E. R. Sharp, F. O. Schoedinger, Robert H. Jeffery and T. J. Kavanaugh. The company manufactures gasoline and electric cars and horse drawn vehicles.

ORGANIZE KELLEY COMPANY.

Will Act as American Sales Agent for Well Known British Manufacturer.

Announcement is made from New York City of the organization of the Kelley Company, which will act as American selling agent for a line of windshield joint fittings and other specialties made by George Beaton & Son, Ltd., London, England. The concern is composed of P. J. W. Kelley, formerly with the Splittorf interests, and James M. Carples, a well known importer.

The Beatonson specialties were formerly made in this country, and are held to be covered by American patents. However, the contract was cancelled for cause some time since. During a recent visit to Great Britain, Mr. Carples learned of this and immediately secured the option on the importing and manufacturing rights, which have been turned over to the Kelley company.

TO INCREASE ITS CAPITAL.

Goodyear Tire & Rubber Company Has Proposition to Add Nearly \$4,000,000.

The stockholders of the Goodyear Tire & Rubber Company, Akron, O., have been notified of a meeting to be held March 3, to act upon a proposition to increase the capital stock of the company by nearly \$4,000,000. This will include the increase of the preferred stock from \$5,000,000 to \$7,000,000. and the common from \$5,038,800 to \$8,000,000.

The financial plan calls for a common stock dividend of 20 per cent.; the sale of \$1,500,000 common stock at par to common stockholders, and the sale of \$2,000,000 preferred and \$500,000 common at par to preferred stockholders. It is understood that the sale of the additional stock has been underwritten.

RETURNS TO ADVERTISING.

E. K. Leach Leaves Oakland Sales Company for Philadelphia Evening Telegraph.

E. K. Leach, who was for some time general manager of the Commercial Car Journal, pub-

lished in Philadelphia, before becoming branch manager of the Oakland Motor Company in that city, has resigned the latter position to take that of advertising manager for the Philadelphia Evening Telegraph. His success as a salesman has been such as to win him a large number of new friends in the industry, and he will carry with him to his new position their best wishes for the future.

It is said that "once a newspaper man, always a newspaper man", and this appears to be true in Mr. Leach's case, since he was formerly for a number of years on the advertising staff of the Philadelphia North American. He also was interested for a time in co-operative and educational campaigns to interest national advertisers in dailies.

MARION RECEIVERSHIP.

Financial Affairs of the Company Have Been Adjusted Satisfactorily.

It is announced from Indianapolis, Ind., that the receivership, under which the Marion Motor Car Company of that city had been working since Nov. 3, 1913, was lifted by order of the court Jan. 24. It was stated at the time the company was placed in the hands of a receiver that the move was merely a protective one, and it is understood that the financial affairs have now been adjusted to the satisfaction of all concerned.

Two new men have been added to the company, these being H. J. Hayes of Detroit and Isaac Kinsey of Toledo, O. Mr. Kinsey will be chairman of the board of directors, which will include the following officers: President, J. I. Handley; vice president, H. J. Hayes; treasurer, J. M. Edsall; secretary, James E. Kepperley. In speaking of the recent court action, President Handley said:

This means that the Marion company will go ahead on a broader basis than ever before. Evidence of the regard in which the Marion is held by dealers and owners is reflected by the fact that our organization was held intact during the receivership. Naturally, we are well pleased with the outcome. We are all hoping that we will have no more floods in Indianapolis, for, as a matter of fact, the company's temporary embarrassment was very largely due to the floods of last March, which resulted in not only great financial loss at the time, but almost entirely disabled our manufacturing organization right at the height of the spring season. This made us over late in finishing our 1913 production, and correspondingly late in starting deliveries of our present models.

The J. I. Case Threshing Machine Company, Racine, Wis., maker of the Case car, will add 4000 workmen as fast as they can be secured, according to advices from that city.

NEW ACCESSORIES FOR THE MOTORIST.

LEE LICENSE HOLDER.

Includes Truss Rod to Prevent Vibration.

The Wm. O. Lee Company, Port Huron, Mich., is marketing the Lee lamp truss rod and license holder. It

is made in two styles, the No. 1 being designed for used cars and the second a special for automobile manufacturers. The former is adjustable, rods sliding into either side of the holder proper, and being locked by a clamp having a locking bolt. This permits the use of the design on different machines.

The device is fitted by slipping the ends of the rods over the lamp bracket, suitable eyes being provided. The clamping members are then secured. The maker states that the parts will not work loose, and that the truss will prevent vibration of the lamps, as the brackets are held in a rigid position. Means are also included for securing the number plate. The lamp truss rod and number plate holder is constructed of high grade material and is nicely finished.

RAY SOCKET WRENCH.

Equipment Includes 30 Steel Sockets, Extension, Etc.

The Ray socket wrench is manufactured by the Packer Auto Specialty Company, Chicago, for which Ralph Walcott, 1790 Broadway, New York City, is distributor. The maker states that the wrench will fit every nut and bolt on a car, and may be utilized in places difficult of access with the conventional tool. The wrench proper is sturdily constructed and when utilized with the universal joint provided with each outfit, it is claimed that work may be accomplished at any angle up to 90 degrees.

The complete equipment includes, in addition to the wrench, which is nickelled and highly polished, a long

extension bar, two short extension bars, one large and one small screw driver bit, one universal joint, one four-inch spark plug socket and 30 case hardened cold drawn steel sockets. These are graduated in sizes and fully guaranteed. This equipment comes in a wooden case, and the maker states that it will perform a variety of work as well as eliminate the necessity of carrying a large number of conventional tools. The company also manufactures a small set which differs from the larger member in that 11 sockets are provided in addition to the spark plug member. The smaller outfit comes either in a leather case or an oak box.

HARTFORD CUSHION SPRING.

Principle Involves Use of Double Spring.

The Hartford cushion spring is manufactured by the Hartford Suspension Company, Jersey City, and the maker states that it is not a shock absorber, but a spring construction, which makes easy riding over moderately rough or other roads where the usual spring would cause discomfort. The Hartford design comprises a pair of double-acting

spiral springs which are attached to the rear shackles, capable of absorbing vibrations not taken care of by the usual shock absorbers.

The Hartford design consists of a spring within a spring, the larger or quick acting member moving freely up and down as the automobile spring expands and contracts. The inner spring serves as an auxiliary member to the other and is slower in its action. The two operate as compression members until a certain point is reached on the return, when it is held that a perfectly easy movement, free from abruptness, is obtained. The components of the cushion spring are housed in a neat metal casing and being compact the design does not detract from the appearance of the car. They are made in five models, including a special design for model T Ford machines, the types varying only in their carrying capacity. They are sold under a guarantee, and it is stated that they can be attached in 30 minutes. The maker of the Hartford cushion springs states that great care has been taken to incorporate only the finest grade of steel.

ZERO PUMP PRIMER.

Mixes Air and Gas for Starting a Motor When Cold.

The Zero pump primer is marketed by the Ideal Brass Works, Tenth street and Canal, Indianapolis, Ind.,

is attached to the dash, and the maker states that it automatically mixes the proper proportions of fuel and air for starting a cold motor. It is connected to main line of supply and the fuel is drawn into the mixing chamber or body of the pump, by the outward stroke of the plunger.

The downward stroke injects a small spray of fuel and air into the intake manifold above the carburetor, and the maker states that the mixture will ignite easily. The device is provided with an automatic needle valve for opening and closing the line when the plunger is operated.

CLARK WINDSHIELD.

Is Fitted to Tonneau and Is Adjustable as Desired.

The Clark adjustable tonneau windshield is manufactured by A. N. Clark & Son, Plainville, Conn., and, as the name implies, is designed to protect the occupants of the rear seats from draughts, rain, etc. One of its qualities is that it may be adjusted as desired, and another feature is that it may be folded when its service is not required, as in warm weather. It is made with a variety of bases to fit any car, and is attached to the seat under the cushion, coming up between the seat arm and the cushion. One windshield is used on either side of the car.

The Clark design is made of aluminum, finished in black, and is not only light, but is substantially constructed. It is pointed out that its use does not interfere with the exit or entrance of passengers, and that communication with the occupants of the front seats is not interfered with.

HERZ TAPE GRIP RING.

Automatically Winds Tape on Hose by Friction Principle.

The Herz patent tape grip ring, manufactured by Herz & Co., 245 West 55th street, New York City, is

a coupling having a metal rim with raised knurled edges, the rim being provided with a slot on one side through which ordinary tape is drawn in when rotated by hand. The rim has an inside flange, permitting the end of the hose to slide against it. In making the coupling the tape grip ring is slipped over the hose and the tape inserted in the slot. By rotating the ring the tape is drawn into the slot, and further movement results in the tape coiling itself upon the rubber of the hose, making a tight joint. This is due to the friction between the hose and the tape being greater than that between the tape and the ring.

NYCO TWO-SYSTEM SWITCH.

Provides Two Circuits on One Kick Switch.

The Nyco two-system switch will appeal to owners of Ford and other makes of cars utilizing a master vibrator in connection with the conventional induction coils for ignition, in that the regular coil may be employed without removing the means utilized for shunting the primary circuit. With the Nyco the switch or controller may be moved to the vibrator side or to the coil side as desired. In the latter position the regular coil is brought into service. This is a distinct advantage, in that it permits the operator to use the vibrators to locate a missing or faulty cylinder. The lever or control member is of the conventional kick type and is operated easily by a simple movement of the foot.

The device is very compact and is constructed with the same care and high grade material for which the products of the maker, the New York

Coil Company, 340 Pearl street, New York City, are noted. It is supplied with flexible wire connections of different colors and of proper length to connect to the master vibrator and those of the coil. The wiring of the car is not changed, and the Nyco may be fitted to the dash and wired in 10 minutes by the most inexperienced person. It is moderately priced and is guaranteed.

JUNIOR GASOMETER.

Dash Gauge Indicating Supply of Fuel in the Tank.

Among the numerous devices for indicating the supply of fuel in the gasoline tank is the Junior Gasometer, made by Oliver C. Ritz-Woller, 538 Clark street, Chicago, who also manufactures the Ritz Gasometer designed for large machines. The device is a compact, circular, dial like member, mounted on the dash, and the principle employed is that of a pneumatic control of the indicator.

The Junior is a smaller form, but operates on the same principle as the more expensive indicator, and the amount of fuel on hand is denoted by large figures. In the accompanying illustration zero is shown, denoting

that the tank is empty, and it will be noted the figure is easily discernable.

The maker states that the Gasometer will indicate every minute and correctly the amount of fuel in the container, whether the car is travelling up hill or down, over rough or smooth roads, as the operation of the device is not affected by the movement of the gasoline in the tank.

It is also claimed that a novice can install it on a car in a very short time. It is adaptable to both gravity and pressure feed systems, but when the latter is employed the price of the Gasometer is slightly increased.

BUYERS' GUIDE.

Readers of The Automobile Journal in need of anything in accessories, equipment, supplies or fittings should consult the Classified Buyers' Guide, found elsewhere in this issue. It provides a handy reference, in that the articles above referred to are listed alphabetically, and the names and street addresses of the makers are given, also their branches or service stations. The concerns listed therein are reliable and are worthy of your patronage.

SAFETY FIRST HEADLIGHTS.

Automatically Turn with Front Wheels, Eliminating Glare.

The Headlight Support Company, Detroit, is manufacturing the Safety First turning headlights for which a

number of practical advantages are claimed. They are of the moving type, being actuated by connections to the tierod of the machine so that when the steering wheel is rotated the headlights are turned in the same direction as the front wheels. The supports are fastened to the frame in much the same manner as the conventional method of attachment.

The particular advantage emphasized by the Safety First device is that in rounding curves and turning corners the road is lighted on the side not illuminated by fixed headlights. Another feature claimed is that in meeting an approaching car the lights may be so turned as to eliminate the glaring effect.

DUPLEX PISTON RING.

Maker Claims Oil and Gas Tight Features.

The Duplex piston ring is manufactured by M. L. Dunham, 140 West 52nd street, New York City, and the maker states that when fitted to a piston the gas cannot pass the rings; that smoking is eliminated and that the efficiency of the motor is improved. One of the qualities claimed for the Duplex is that wear does not affect the joints. It is also stated that it remains sealed at all times.

It is further held that the tension of the ring is balanced or even, and that its gas tight feature is obtained with a very light pressure. When in service the ring has an outward tension, also a double spiral tension; that is, the free ends not only exert a force outwardly, but expand radially in opposite directions around the cylinder wall, and will fit themselves to a worn or new cylinder.

MODEL A CAM JACK.

Has Long Handle and Is Quick Acting.

The Cam Jack is the product of the Four-Wheel Auto-Jack Company, 146 Madison avenue, Reading, Penn.,

and is made in two models, that illustrated being the A design for light cars weighing 2000 pounds and under. One of the qualities of the jack is that a long handle permits of placing it under the car without stooping, and a single push performs the work of lifting. It has an instantaneous adjustment to varying axle heights, making for economy in time. An automatic stop is incorporated, locking the lever at the end of the lift, and a quick drop is obtained by throwing back a pawl and stepping on the handle.

THURBER AIR STARTER.

Air Pump and Starter Combined in a Unit Construction.

The Thurber Rotary Starter Company, 685 Atwater street, Detroit, has brought out a new model Thurber rotary starter, which is operated by compressed air. The pump employed is of the high pressure type and one of its features is that it is built with the starter, a unit construction. The starter is mounted at the front of the machine, on a cross frame member, and being very compact, does not detract from the appearance of the car. The pump is held to be very efficient in its action and makes it possible to carry a pressure of 250 pounds at all times. The air is stored in a drawn steel tank located out of sight beneath the body. The system includes a gauge mounted on the dash, which indicates the supply of air in the tank, and provision is also made in the dash plate valve for an outlet for connecting a hose for the purpose of inflating tires, cleaning, etc.

Two control units are mounted in the floor or toeboard, these comprising the starting button and pump control pedal. The gasoline motor is started by depressing the button, which actuates a rod connected to a double control valve, permitting air to flow from the tank to the starter which, being attached to the crankshaft, spins the last named member. Upon the engine starting under its own power a clutch disengages the starter, which remains idle until another start is desired. The tank is refilled by depressing the pump control pedal.

K-W ROAD SMOOTHERS.

Designed Especially for Model T Ford Automobiles.

The K-W Ignition Company, Cleveland, O., is manufacturing the K-W road smoothers for the model T Ford automobile and the company states that they are not shock absorbers. It is held that the tires may be pumped up to the maximum pressure without affecting the resiliency, as the K-W has a cushion effect, taking up vibration, shocks, etc.

The smoothers come four to a set, being utilized both front and rear, and, as will be noted by an accompanying illustration, comprise a simple arrangement of a spring hanger

with an additional coil spring which is substituted for the regular Ford spring hangers. The K-W springs support the regular members and it is held that they are anti-synchronous with them, but do not retard their action.

It is stated that the smoothers may be attached without drilling or any other alterations. All that is necessary is to relieve the springs of the weight of the car, displace the spring hangers, place the smoother in position and shackle the end of the main spring to the K-W device. They are guaranteed for one year.

NEW ACCESSORIES.

The Automobile Journal invites manufacturers, distributors and agents to co-operate in presenting to its readers new accessories, equipment, etc. The forwarding of suitable illustrations and data, and publishing of same, does not place the contributor under any obligations. The editor of this department, however, reserves the right to discuss the practicability of the article submitted. The name of the manufacturer and street address, should accompany all data, also retail price.

HALL PILLAR LAMP.

Illuminates Steps or Running Board of Enclosed Car.

The C. M. Hall Lamp Company, Detroit, is marketing the Hall "223" pillar lamp, which is a handsome de-

sign of the electric type. It is employed both for a side and step light, as a reflector is incorporated over the bulb, which throws the rays downward on the step or running board to be illuminated.

The lamp is designed for limousine bodies, and it is stated that the rays do not shine in or blind the eyes of passengers entering the car. The lamp has a hollow bracket through which the wires are passed into the body and to the main lighting circuit.

GRAY & DAVIS DIMMER.

Headlight Is Equipped with a Large and a Small Bulb.

In many cities the ordinances prohibit the use of headlights or lamps which blind those approaching the machine. This necessitates the turning out of the headlights and utilizing the side lamps. To comply with the laws and to provide both the side and headlight in one unit, Gray & Davis, Inc., Boston, Mass., has brought out a dimming attachment.

It comprises a four candlepower bulb mounted at the top of the reflector, and in such manner that it does not impair the efficiency of the centre or regulation bulb. When the lighting switch is turned to "All On" or "Headlights and Rear", the small bulb remains unlighted, but when the switch is moved to the "Side and Rear On", the small lamp is lighted and the larger member extinguished. This attachment, which is provided at a slight extra cost, is also of value when driving in the country.

MANY REFINEMENTS IN 1914 WHITE LINE.

BELIEVING that the interests of its customers are best served by refining principles indorsed by sound engineering practise and main-

shield, convenient to the operator, and comprise a starting and lighting switch, and the battery indicator. The White motor-generator is a com-

White Thirty Roadster, Having a Long Stroke Motor, Four-Speed Gearset, Electric Lighting and Motor Starting, Etc.

taining the high standards characteristic of its product in the past, the White Company, Cleveland, O., maker of the White cars, announces the retention in 1914 of all three chassis. These are the Thirty and Forty, four-cylinder designs, and the Sixty, a six-cylinder model. A number of improvements are noted in the chassis, these being in keeping with the policy of the company to add conveniences as soon as they are developed and perfected. The prices remain unchanged, but the improvements give each model a higher value, and this applies both to the chassis and body.

Particularly noticeable is the use of a molding around the top of the bodies of the Sixty models, which adds to their attractiveness. The enclosed types have been redesigned, the shape of the roofs being more graceful, while the body trimmings represent the highest development of the coach maker's art. The new touring bodies are built on long, straight lines with a full curved rear, and the dash has no cowl. Instead, the top lines of the hood and body extend in an almost unbroken line. All fittings, such as door handles, hinges, etc., are of the concealed type. The windshield presents a neat appearance and is supported by rods attached to the body.

The control units have been centralized and simplified. They are mounted in an aluminum receptacle built into the dash just below the wind-

compact unit, and one of its qualities is that stalling of the engine in service is automatically prevented by the arrangement of the system as, upon the speed of the engine falling to a predetermined point, the electric motor becomes operative, supplying energy until the engine operates under its own power. The change from a motor to a generator is performed automatically. This automatic cranking feature is a distinct advantage when operating in crowded traf-

fic. The headlights are of the double-bulb construction, a miniature lamp supplying the dimming feature and eliminating the conventional side lamps.

The White line of enclosed cars will appeal to those who appreciate the luxury and comfort provided by rich fabrics and deep upholstery. Coupe bodies are fitted to the Thirty, Forty and Sixty. The coupes are of the colonial type with sloping roof, and the design is well balanced by the graceful outline of the rear compartment, which permits ample storage space. The seating capacity provides for three persons, two on the rear seat and one in front at the right. The interior fittings include dome light, Pullman reading lamps, coat hooks, umbrella holder, ventilator, bouquet case, toilet case, hat and parcel rack, cigar lighter and those conveniences in keeping

The Chassis of the White Forty Has Been Lengthened to 124 Inches and the Stroke of the Motor Increased.

with the enclosed type of body. The limousine bodies are beautifully upholstered and the appointments are in keeping with the design. The

driver is enclosed, separated from the passengers by a glass partition, which may be lowered into the wall to provide a unit interior.

The White Thirty Touring Car for 1914 Is Noticeable for a Number of Improvements and Refinements.

Among the mechanical improvements is the adoption of a single plate clutch running in oil, instead of the leather faced cone used heretofore. The change was not due to any dissatisfaction with the cone, but was made owing to the superiority of the White design, which is held to operate with remarkable smoothness.

Although the cooling system has always been efficient under the severest kinds of service, a new design of water passage from the top of the water jackets to the radiator is utilized. This water head combines the outlet cover plate and pipe. The honeycomb radiator is continued but is of larger capacity.

The White motors are cast en bloc and are in the long stroke class. The dimensions of the Forty have been increased, the bore being 4.25 inches and the strokes 6.375. The Thirty has a bore of 3.75 inches and stroke of 5.125, while the cylinder dimensions of the Sixty are 4.25 by 5.75.

Carburetion is by a White carburetor, water jacketed and connected to take the heat of the exhaust. The single system of ignition is employed, a high-tension magneto. Cooling is by a gear driven centrifugal pump, aided by an adjustable belt driven fan. Lubrication system is a combination force feed and splash. There is a direct feed to the main bearings, and each connecting rod is lubricated through oilways, drilled through the crankshaft. The oil is circulated by a gear driven pump, actuated by the camshaft. The reservoir is secured

to the right side of the cylinders, and there is an oil level valve on the under side of the crankcase, which is operated by a pull rod fastened under the radiator. The supply of lubricant is adjustable at the pump and a sight feed is located on the dash.

The White gearset provides four forward speeds as in the past. It is of the selective type, the gears of heat treated chrome nickel steel, and all shafts are suspended in annular ball bearings. Direct drive is the third speed, the fourth being a step-up. Drive is through a shaft of ample size, having two universal, and one telescopic, joints to the rear axle, which is a

White design. Two sets of brakes are fitted, the service being of the external contracting type, operating by pedal, and the emergency metal-to-metal, internal expanding.

The front axle is a one-piece drop forged I beam section type, of high carbon steel, heat treated. The rear axle is a White design. The differential and axle sleeves are supported by a heavy truss extending under the differential housing, and all gears are accessible through a removable cover. The live axles are of chrome vanadium steel, heat treated. The brake band supporting arms are integral with the axle sleeves.

The front springs are semi-elliptic and rear three-quarter elliptic. The company calls attention to the easy riding qualities of its springs,

The White Berline Is Not Only a Handsome Design, but Is Richly Appointed—Among the New Features Is a Step Illuminating Pillar Lamp.

which are of a special steel alloy. The wheels have unusually large hubs and spokes, and annular bearings are utilized. Demountable rims,

with one extra member, are standard equipment on all models. The tire sizes are as follows: Thirty, 34 by four; Forty, 36 by 4.5; Sixty, 37 by

White Six-Cylinder, Seven-Passenger Touring Car—A Single-Plate Clutch Replaces the Cone, and the Cooling System Has Been Improved.

five. The wheelbase of the Forty chassis has been increased from 120 inches to 124. That of the Thirty is 110 inches. The six-cylinder models have a wheelbase of 132 inches. The driver is placed at the left in all models. As in the past the White company thoroughly protects the mechanism of the chassis, the components of which are very accessible for inspection and adjustment.

ENTRIES NOW NUMBER SIX.

Anel Is Withdrawn in Favor of Two Centipedes with 16 Valves Each.

It begins to look as if the fourth international sweepstake, or 500-mile, race on the Indianapolis motor speedway, Memorial Day, would bring out a number of new racing models. Thus far, but six official entries have been made, and of these the two Stutz cars are about the only names that appear at all familiar. There is also a Gray Fox, and there was a Fox machine entered last year. The others are designated as the Beaver Bullet and two Centipedes. The Anel has been withdrawn and one of the Centipedes has been entered in its stead.

These Centipedes are entirely new, and, while complete details are lacking as yet, it is anticipated that they will present some novel features. The motor dimensions are given as 5.1-inch bore, 5.5-inch stroke, and 449.43 cubic inches piston displacement. The last named figure would in-

dicate a four-cylinder engine, but it is stated that the name of the car is taken from the fact that the motor has 16 overhead valves. Robert Burman will drive one of the Centipedes, but the driver for the other has not been nominated.

From Europe comes the information that no less than seven foreign drivers and cars may be expected, as follows: Alfred Guyot, Delage; Jules Goux, Peugeot; Georges Boillot, Peugeot; Jean Chassagne, Sunbeam; Arthur Duray, Peugeot; Felice Nazzaro, Nazzaro, and Christiaens, Excelsior. These cars represent France, England, Italy and Belgium. Other American and foreign made machines are expected in early announcements.

In recent descriptions of the new Continental Baby, model N, engine, made by the Continental Motor Manufacturing Company, Detroit, a typographical error made it appear that the valves in this motor were only 1.0625 inches in diameter. As a matter of fact these valves, in both the model N and the Baby Six, model 6-N, are held to be exceptionally large for the cylinder measurements, being 1.75 inches. The bore of these engines is 3.5 inches and the stroke five. The company states that this large valve equipment is in accordance with the latest practise, as evolved by automobile engineers in this country and

The White Thirty Three-Passenger Coupe Has Attractive Lines and the Appointments Are Most Complete.

abroad, and that it secures for the motor a much freer action and considerably raises its effective output at high speeds.

NOVEMBER IMPORTS AND EXPORTS.

FOR the first time in a number of years the monthly report of the Department of Commerce for November shows a decrease in the valuation of automobiles shipped abroad for the month over the corresponding month for the previous year. In number of cars, there was a slight increase, and if the valuation of parts be added to that of the machines, another increase appears.

The number and valuation of imports for the month shows a slight increase over the month of October, which was the first under the so-called Underwood tariff. This feature of the report is unusually interesting, in view of the application of the new tariff, because it would appear that the average price of the cars coming

November, 1912, was \$1050, as against \$982 for the same month in 1913. The 31 trucks mentioned above were valued at \$56,176, and the 64 at \$105,501. The detailed figures for the month of November and for the first 11 months of the respective years are given in the accompanying table.

into this country from abroad was growing slightly less.

During October there were imported into this country 29 cars, valued at \$74,646, while during November, there were 37 cars valued at \$77,773. This gives an average valuation of \$2574 for the former month and \$2102 for the latter. The average valuation of cars coming into this country in 1911 was \$2153; in 1912, \$2268, and for 1913, previous to the application of the new law, \$2332.

The export figures show that of the total of 1771 machines shipped abroad in November, 1913, 64 were commercial vehicles and 1707 pleasure cars, as against 31 trucks and 1658 pleasure cars during November, 1912. The average valuation of the pleasure cars shipped abroad in No-

troit, attended the annual convention at the factory last month. A feature of some little interest was the annual banquet at the Hotel Cadillac, during which a one-act play, written expressly for the occasion, was enacted by dealers and factory representatives, the plot being a burlesque of the eccentricities of both dealers and factory officials.

At the conclusion of the dinner the National Federal Dealers' Association was organized with the following officers: President, Allan Baker, St. Louis, Mo.; vice president, William L. Hughson, San Francisco; secretary, C. T. Chenevert, assistant sales manager, with headquarters in New York City, and treasurer, H. S. Dunlavy, Chicago.

WITH THE MOTORING INTERESTS ABROAD.

German, French, British and Belgian Manufacturers Co-Operate in Arranging Show Plans---Analysis of Hornsted's New Records---Other Foreign News.

EUROPEAN motor car manufacturers have been giving the annual show question some very earnest thought during the past few years, and it would appear that they have evolved an entirely new plan with respect to holding such exhibitions in Germany, France, Great Britain and Belgium. It is stated that the national organizations of manufacturers in these four countries have banded themselves together under the name of the International Union of Automobile Manufacturers for the purpose of regulating the shows held in Berlin, Paris, London and Brussels, and that a meeting will be held in the near future to put these plans into execution.

It will be remembered that the French manufacturers abandoned the Paris Salon for a time, this annual display having been revived in 1912. The German manufacturers abandoned the annual Berlin show in 1911, and none has been held since. The Brussels show, which was held last month, has not been regarded as of quite the same importance as the others, and the annual Olympia show in London is practically the only

be held early in December, instead of January as heretofore. This order has been determined upon because the French and British makers already had engaged their buildings for the dates named.

In each city the same plan will be followed in the matter of drawing for space. Locations will be determined by lot, manufacturers representing foreign countries having equal rights with those of the home country, providing they have been represented in three previous shows in that city. If this requirement has not been fulfilled, then foreign firms draw immediately after the home manufacturers in their respective classes.

HORNSTED'S WORLD'S RECORDS.

New British Marks Do Not Exceed Those Made by Cars in This Country.

Some little interest attaches to the new world's straightaway records recently set up by Hornsted of Great Britain in a Benz car on the Brooklands track at Weybridge, England. In various quarters these have been hailed as indicating the fastest speed yet attained by a motor car. A little study of the British world's records and those accepted by the American Automobile Association should be sufficient to convince the investigator that Robert Burman has not been robbed of his honors in this field.

Hornsted drove his Benz car over a measured kilometer on the Brooklands track in one direction in 29.62, and in the reverse direction in 31.19. Records are not accepted abroad unless the course is driven in both directions, and then only the mean time is taken. In this case the record has been accepted as 30.405. It may be explained that this was for a standing start. Burman drove his Blitzen Benz over a measured kilometer on the beach at Daytona, Fla., April 23, 1911, in 15.88, but his was a flying start. It is only on the score that Hornsted's mark was for a standing start that it can be recognized generally as a world's record.

Hornsted drove a measured half-mile, also from

COMPARISON OF BRITISH AND AMERICAN WORLD'S RECORDS.

	Kilo	.5-mile	1 mile	2 miles	5 miles
Hornsted, Benz, Brooklands	29.62	25.49	57.99	2:35.00
Burman, Benz, Daytona	15.88	25.40	51.28
Hemery, Darracq, Daytona	2:34.00
Burman, Benz, Indianapolis	21.40	16.80	35.35
Bragg, Fiat, Los Angeles	1:15.96

one of the four which has retained its position as an international exhibition from the beginning.

Apparently, the International Union of Automobile Manufacturers is seeking to reduce the expense attendant upon exploiting the season's models in this manner. And to this end, it is proposed to hold the international displays in the four countries named early in the season and closely enough together to enable the use of the same cars and chassis for all four exhibitions.

Thus the 1914 Berlin show will be held in October, probably Oct. 1-10, to be followed Oct. 16-26 by the Paris Salon. The Olympia show will be opened Nov. 6, and it originally was the intention of the Society of Motor Manufacturers & Traders to extend the show period to 10 days instead of a week. This plan may be changed, but it is anticipated that the Brussels event will

a standing start, in one direction in 25.49, and in the other in 25.60, with a mean time of 25.545. Burman drove the Blitzen Benz a measured half-mile on the Indianapolis speedway, May 29, 1911, in 16.80, but this was from a flying start.

However, Hornsted claims two world's straightaway records made from a flying start. He covered a measured two miles on Brooklands track in 57.99, but this was nearly six seconds slower than the 51.28 made by Burman at Daytona, Fla., April 23, 1911. It does exceed the flying two miles made by Caleb Bragg in a Fiat on the Los Angeles motordrome, April 13, 1910. Bragg's time was 1:15.96.

The other record claimed by Hornsted is for the flying five miles, held in this country by Victor Hemery in a Darracq, and made at Daytona, Fla., March 24, 1909. Hemery's time was 2:34.00, and Hornsted's 2:35.00.

The situation is set forth in a graphic way

in addition of three new models of Knight engined trucks brought out abroad. And it may be added, that it is expected that at least one American manufacturer will shortly announce a commercial vehicle utilizing this type of engine.

So far as is known, the Daimler Company, Coventry, England, was the first concern to utilize this type of engine in a motor business wagon. It brought out its first machine, rated at one-ton capacity, about a year ago, and, although it was expected that it would meet with a certain amount of prejudice, the year's results have been most satisfactory. Several Daimler-Knight omnibuses are running in London and other English cities, and several wagons have been working on all kinds of roads and in the hands of skilled and unskilled drivers.

The Daimler Company now announces two additional models, one of which is shown herewith. This is rated at two tons, and the other has

Two-Ton Daimler Truck Chassis, Equipped with Four-Cylinder Knight Engine and Worm Driven Rear Axle.

by the accompanying table. The only explanation lies in the supposition that Great Britain refuses to accept the marks made in the United States, although these have been recognized generally for several years. It seems decidedly evident that Hornsted has not yet travelled faster than any one else in a motor car.

KNIGHT ENGINED TRUCKS.

Daimler Company Adds Two More Models and Minerva Concern Enters the Field.

Because of the interest created in the Knight engine by the recent world's record test of the Moline-Knight motor, made by the Moline Automobile Company, East Moline, Ill., in the laboratory of the Automobile Club of America, New York City, a matter of timely notice is the

capacity of five. They are very much alike, with the exception of the engine size and the size of some of the other components. Both motors are of the four-cylinder type, the larger having bore of 110 mm and stroke of 150 (4.3 by 5.9 inches), and the smaller, 95 by 125 mm (3.7 by 4.7 inches). The former is rated at 30 horsepower and the latter at 22.4. Both machines are fitted with large diameter cone clutches, and the selective sliding gear transmissions afford four speeds forward and reverse. Final drive is by shaft, fitted with leather disc universal joints, to a worm driven rear axle.

The maker of the Minerva car in Belgium, which has been utilizing Knight engines in its pleasure car models for some time past, has also brought out a truck of 2.5 tons capacity, fitted with this type of motor. The engine is a four-cylinder unit, with 85 mm bore and 140 mm

stroke (3.3 by 5.5 inches), located in the cab. The transmission affords four forward speeds and reverse, and the final drive is by shaft to a worm driven rear axle of the overhead worm type.

RUNNING CARS ON POTATOES.

Great Britain Is Much Interested in Possibilities of Alcohol as Fuel.

It is now some years since the first suggestion was made that potatoes and like crops could be made to produce a fuel suitable for use in automobile engines, but the idea seems to have been revived with energy in Great Britain. The Autocar, a British motoring publication of prominence, has engaged Dr. W. R. Ormandy to conduct a series of tests utilizing alcohol as fuel, and it is stated that these already have resulted in showing that a half-and-half mixture of alcohol and benzol will work satisfactorily with ordinary gasoline engines and carburetors; that with slightly modified engines and carburetors this mixture may be used even more advantageously, and that with specially designed engines and carburetors alcohol alone could be used.

In a recent issue of The Autocar, Dr. Ormandy utilized considerable space in reviewing Bismarck's successful attempt to encourage the farmers of northeastern Germany in the production of potatoes on waste land, and their conversion into alcohol. Having established this enterprise the German government still further sought to foster the industry by offering bounties and encouraging the offering of prizes for the manufacture of motors for agricultural purposes designed to run on denatured alcohol, containing about 2.5 per cent. of benzol.

Dr. Ormandy's view of the situation is that German automobile manufacturers did not become interested in the project largely because more than half of the output was sold abroad, and an engine or a carburetor designed for the special conditions of their own home made fuel would have been useless outside their own borders. He states, however, that the government attempted to enforce the use of alcohol-benzol mixtures on the hackney automobile carriages in Berlin, but without notable success, although agricultural motors were constructed which used the fuel successfully.

Apparently, The Autocar and Dr. Ormandy are convinced of the possibilities of alcohol as a motor car fuel, and the series of tests is expected to reveal much additional information. It is conceded that the fuel problem is much more acute

in Great Britain and abroad than in this country. The Institution of Automobile Engineers in England has taken up the subject in an effort to learn exactly what steps must be taken in order to utilize alcohol successfully. At present, however, there is an excise tax on the production of alcohol, and motorists are strongly urged to seek its repeal.

NEWS NOTES FROM FOREIGN LANDS.

The Austrian Imperial Automobile Club's Alpine tour for 1914 will start from Vienna, June 11, and will occupy 10 days.

The Hungarian Imperial Automobile Club, Budapest, Hungary, is said to be organizing a competition for engine starting devices.

The Willys-Overland Company, Toledo, O., has secured an order through its London representative for an Overland car for the personal use of Prince Alfonse of Bavaria.

S. F. Bowser & Co., Fort Wayne, Ind., has been commissioned by King George of Great Britain to install one of its underground gasoline storage systems at the garage at Buckingham palace.

The technical committee of the Belgium Automobile Association is holding a public competition and test of lighting systems Feb. 9-11. Provision has been made for three classifications, electrical, acetylene and miscellaneous.

It would appear that the last record run between Sydney and Melbourne, Australia, had been run, since the police authorities have issued an order that no more attempts are to be made under pain of severe punishment.

It is stated that Prince Henry of Prussia is much interested in a revival of the Anglo-German reliability trial for the Prince Henry trophy some time during the present year. A meeting of the German Imperial Automobile Club was held recently to take up the matter.

A movement is on foot in Australia to construct in the vicinity of Sydney a motor speedway, along the lines of the Brooklands track at Weybridge, England. The proposed track will be 100 feet wide and 2.5 miles in circumference. Brooklands is about 2.75 miles to the lap.

Twenty-one entrants have filed their intention of competing in the Coupe de Tourisme endurance test, leaving Paris, Feb. 15, and covering 2000 miles of French roads. The event is open to small, light cars and cycle-cars only, and will prove a strenuous test of their capabilities, since they will be required to negotiate Alpine passes and Pyrenean gradients, with the equivalent of four passengers aboard.

Thirty-seven cars have been entered for the annual Tour de France reliability test, which will start from Paris, March 1. Unlike previous tests, runs will alternate with hill climbs and speed trials, these to be held in the vicinity of various large towns in order to give the provincials an opportunity to inspect the machines and learn of their possibilities. Toward the end there will be a 60-mile speed contest over the Le Mans course, utilized last year for the Grand Prix.

The following American cars were represented at the recent Northern England show at Manchester: Bedford Buick, Cadillac, Ford, Hupmobile, Overland and Seabrook R. M. C., the last named being the British term for the Regal. In addition there were several American made accessories, included among which were: Stewart speedometers, Bowser gasoline systems, Raybestos brake lining, Jones speedometers, Klaxon horns, Rushmore electric lighting systems, Vacuum Mobiloids, etc.

Early last year the Royal Automobile Club of Great Britain issued rules and regulations with regard to a trial of electric lighting equipment for motor cars which was to be held in competition for a cup to be presented by Country Life. The entry list remained open until Sept. 15, and the trial was to have taken place during October. Inquiry as to the result of the competition reveals the fact that no entries were received. This is somewhat surprising in view of the increasing interest in electric lighting among manufacturers and motorists in Great Britain.

HINTS FOR NEW CAR OWNERS.

Operation of Abbott-Detroit Lubricating System---Adjustment of Model 79 Overland Carburetor---Replacing Camshaft of Model T Ford Motor.

THE Abbott Motor Company, maker of the Abbott-Detroit motor cars, makes several excellent suggestions with reference to the care of the lubricating system of its models C 44, D 34-40 and E 44-50. The first is to purchase the highest grade of lubricant on the market; second, to remove the old oil every 1000 miles and clean the system, and the third is to maintain the level of supply.

The principle of the lubricating system used by the company is shown in an accompanying illustration, the view at the left depicting the float in the reservoir and the high and low level

the old lubricant is to be removed and replaced by new.

The system is classified as a constant level splash with a positive plunger pump to circulate the lubricant, and it cares for every bearing, gear, etc. The two positive plunger pumps are actuated by an eccentric on the camshaft, these supplying a constant stream of oil to the timing gears and rear main bearing, as will be noted by the oil leads. The overflow drains into four separate compartments into which the ends of the connecting rods dip or splash.

A predetermined or constant level is main-

Lubricating System Employed on Models C 44, D 34-40 and E 44-50 Abbott-Detroit Cars.

of the indicator. The sketch also shows the oil plunger pump, valve and the screen utilized to filter the lubricant.

The drawing at the left depicts a section of the crankcase, also the method of feeding the lubricant to the splash compartment. The overflow or stand pipes are shown in the larger drawing.

The supply is replenished through the breather pipe, which is provided with vanes to prevent the crankcase compression blowing out the oil mist. The indicator or gauge is located on the right hand side of the engine, between the second and third cylinders, and the proper level to maintain is between the high and low points. Above the high is not recommended. About .375 inch below the mark indicated is held to obtain the best results. With the level at the proper height there will be about 8.75 quarts of oil in the reservoir, a point worth considering when

tained by the use of overflow or standpipes, by means of which any excess lubricant drains into the sump, but it is screened before it is circulated by the action of the pumps. The object of employing separate compartments for the connecting rods is to prevent the oil from flowing to the rear of the crankcase when the car is ascending grades, a condition which would result in flooding one section of the crankcase and starving the working parts in the forward portion of the motor.

At least every 1000 miles the plug in the side of the lower half of the crankcase should be removed and all the old lubricant drawn off. It is suggested that it be examined carefully for any evidence of metal, which, if present, will indicate trouble. The screen should also be thoroughly cleaned before replacing. At least once a season the lower half of the crankcase

should be removed for cleaning and inspection.

The oil indicator assembly is located on the right hand side of the motor, midway between

Sectional View of Model 79 Overland Carburetor, Showing Its Only Adjustment, the Auxiliary Air Valve Spring.

the front and rear supporting arms. The indicator glass and cover are mounted on the crankcase, and the guide on a metal plug in the bottom of the oil pan. By unscrewing this plug, the float and pointer can be removed. Care should be taken not to bend the wire as it will bind and will not indicate correctly the supply of oil on hand.

OVERLAND 79 CARBURETOR.

The carburetor utilized as standard equipment on the model 79 Overland car is the latest type Schebler, which was designed for the Willys-Overland Company by the Indianapolis concern. It embodies practically the same principles of the model R Schebler, and differs from the earlier types in that the needle valve is actuated by the auxiliary air valve, a lever connecting the latter and the needle. This construction is a pronounced variance from other Schebler carburetors which employ a cam for lifting the needle and proportioning the fuel emerging from the jet to the air.

The Overland carburetor shown in an accompanying illustration has but one adjustment, whereas some Schebler designs have three fuel and one air adjustments. In the Overland design the regulating of the auxiliary air member controls also the emergence of the fuel from the jet, and by referring to the drawing the operation of the lever may be discerned with a little study. It will be seen that one end of the lever is mounted above the auxiliary air spring, while the other is attached to a bell crank lever. The

connections are so made that upon the auxiliary spring being depressed, the lever will lift the needle valve from the jet, augmenting the supply of fuel.

The supply of air at low motor speeds is obtained through a fixed or constant air intake, being drawn in by the suction of the piston. This primary air is taken in through the hot air intake and the proportions of gasoline and air are determined by the position of the needle valve to the jet, which is located in the venturi tube.

There is but one place for the owner to adjust, this being the auxiliary air member, which is rotated to the right or left to alter the adjustment. Turning the knurled sleeve to the right increases the tension of the spring, so that a greater suction will be required to open the air valve, and consequently, the mixture will be enriched, and up to certain speeds less fuel will emerge from the jet. Rotating the sleeve to the left decreases the tension of the spring, allowing the air valve to open more easily, and weakening the mixture because of the increase of air. As previously pointed out, the lowering of the end of the lever attached to the auxiliary air valve spring, raises the needle valve, while lifting it restricts the emergence of the fuel from the jet.

With the Overland carburetor the proportions of fuel and air at high speeds are secured automatically by the auxiliary air spring, which is a compensating device in that it is actuated by the suction of the piston. The design makes for simplicity in that the owner is not required to alter the proportions of fuel and air to meet the

Showing Position of Exhaust Cam, Valve, Crank, Connecting Rod and Piston of First Cylinder of Model T Ford Motor When Gears Are Removed.

requirements of the motor at different speeds.

Steering post control is a feature of the carburetor and it will be noted that a Bowden wire

is connected to the bell crank lever actuating the needle valve. The other end of the cable leads to the steering column, permitting the driver to lift the needle and enrich the mixture for starting, as well as regulate to a certain extent, the supply of fuel.

If for any reason it is necessary to alter the proportions of fuel and air, the auxiliary air sleeve should be turned but slightly until the desired result is obtained. The Willys-Overland Company states that it is best suited to the motor having been subjected to exhaustive tests before being adopted. As with all types of carburetors it is an excellent plan to occasionally open the drain cock and run off a small quantity of fuel. This will remove any water or sediment that may be in the fuel. If the carburetor is suspected of being flooded, open the petcock and with the ignition cut out, crank the motor.

FORD CAMSHAFT SETTING.

With the four-cycle internal combustion engine utilizing poppet valves, the valves are opened by the cams of the camshaft, which raise the pushrods and overcome the tension of the valve spring. The camshaft is provided with a gear, which is in mesh with a gear on the crankshaft of the motor, as shown by an accompanying illustration, which depicts the arrangement of the valve mechanism of the model T Ford motor. Normally, and when the valves are not admitting the mixture or permitting the burned gases to pass out, they are held seated by a spring.

The opening, closing, etc., of the valves is termed the timing of the motor, which is determined by the designer of the engine and is obtained by placing the cams on the camshaft at certain angles, and by maintaining a fixed relation between the camshaft and the crankshaft, by means of gears. When the shafts are assembled the crankshaft gear is so meshed with the camshaft gear that the cams of the last named will lift the valves at regular intervals.

For example: With the Ford engine the inlet valve is supposed to start to lift when the piston has completed the exhaust stroke and has travelled downward .125 inch on the suction stroke. The exhaust valve opens .25 inch before the piston completes the firing stroke. It is important that this timing be observed if maximum efficiency is to be obtained from the motor.

The proper meshing of the camshaft gear with that of the crankshaft member is a simple matter if the teeth are marked, which is generally done by the workmen at the factory. This

makes it easy to replace the shafts correctly in the overhaul of the motor, but should either marked tooth become broken through an accident, the replacing of the new gear and its meshing with the crankshaft member would be made by observing the following:

Rotate the crankshaft of the motor until the piston of the first cylinder is in the position shown in the drawing, which denotes that it has not completed its stroke. The crankshaft rotates clockwise, but the camshaft revolves in an opposite direction, as will be noted by the arrows. Replace the camshaft and mesh its gear with that on the crankshaft so that the exhaust cam is in the position indicated in the drawing. It should be borne in mind that the timing can be checked by utilizing the timing diagram of the motor, which is as follows:

Inlet valve opens .125 inch (piston travel) past top dead centre and closes .25 inch past lower dead centre. Exhaust opens .25 inch before lower centre and closes on top dead centre. When the valves are seated or between the periods of opening and closing, the space or clearance between the pushrods and valve stems should be .03125 inch. If more exists, it should be reduced, by utilizing valve stem adjusters, which may be obtained at any supply house carrying Ford accessories.

DISCOVERS NEW FUEL.

Will Require Special Carburetor, as It Is Too Heavy for Those Now in Use.

H. T. Cauller of Trenton, N. J., claims to have evolved a new automobile fuel, which he says can be produced with less expense than gasoline and possesses three times the power and efficiency of any fuel now used. He has named it "power and efficiency oil" and says that it is produced by a blending of various oils under a secret process.

The new fuel is described as a jelly like substance, and the inventor says it will be necessary to construct a special carburetor as it is an emulsion far too heavy to be carburetted successfully with the present instruments. He has filed an application for a patent, and believes he can produce the fuel to sell at 13 cents a gallon.

The Dunlop Wire Wheel Corporation of America has located its factory in Long Island City, N. Y., where it will manufacture the Dunlop wire wheels under license from the foreign concern.

gress of March 3rd, 1879.

DEFINING A CYCLECAR.

The cyclecar branch of the automobile industry in America is hardly more than six months old. Undoubtedly, experimentation has covered a much longer period, but the first announcements made their appearance in June or July, 1913. The instant response in public interest was such as to cause the makers of numerous types of machines to list their product as cyclecars, although probably the generally accepted idea of a cyclecar was that of an automobile built along the simplest possible lines and with a narrower tread than standard.

During the last week in January, the Cyclecar Manufacturers' National Association was organized in Chicago, and its first business was that of adopting a definition intended to accu-

ately describe a cyclecar as such. The result really has been to divide all so-called cyclecars into three classes—true cyclecars, light cars and small cars—since membership in the association apparently is limited to manufacturers of machines with motors having piston displacement of 125 cubic inches or less and with weight of 1150 pounds or less. No mention is made of tread or other factors than these.

The terms light cars and small cars are not new. They were applied to automobiles long before the cyclecar movement was inaugurated. A few machines of standard tread now listed as automobiles, and never designated by their makers or regarded by others as anything else than automobiles, have piston displacement which would place them in one or the other of the two larger cyclecar classes.

The definitions adopted by this new association may be regarded an excellent working basis for further consideration, but unless some action is taken to more accurately describe these classes, additional confusion will result. It would appear that the whole matter must be taken up by the National Association of Automobile Manufacturers before the definitions can be accepted as final. And the present status of the cyclecar situation would seem to indicate that the sooner this action was taken the better.

NO COMPROMISE IN OHIO.

The Ohio State Automobile Association is to be congratulated upon the stand it has taken with reference to the attempt to patch up the so-called Warnes law so that it will comply with the constitution of the commonwealth. There is to be no compromise on the part of the association, its members reserving the right to attack any law that may be passed in the courts.

In the first place, automobile registration can be defended only upon the ground that it is based upon the police powers of the state. United States courts have held that when the fee is made larger than is sufficient to meet the expense of administering the law it becomes a tax. Some day this proposition will be carried to a court of last resort, and a definite conclusion reached, but at present the Ohio State Automobile Association is amply justified by the decisions in Ohio, Michigan and Mississippi, in the position that there is no reason for compromising.

ROAD CONSTRUCTION WITH REFINED TAR.

A Discussion of the Several Steps Taken by Massachusetts Highway Commission in Building State Roads Having Even Riding and Even Wearing Qualities.

ORGANIZED motorists have been instrumental in awakening widespread public interest in the matter of road construction and

Plant for Crushing Field Stone of Granite and Trap Rock.

maintenance. Automobile owners have a two-fold reason for studying the subject, the first being the added economy in operating machines over improved highways, which also involves the increased efficiency, not only of the automobile, but of any type of road vehicle. This point having been proven to the general satisfaction of all who have occasion to use public ways, the next step is to consider the proper application of funds which may be appropriated or assigned to such purposes. And here the motorist must have deep concern, because he is called upon to assume a large proportion of the expense of such work, both through the direct taxation of property and the indirect taxation imposed by registration fees, etc.

Massachusetts has long been regarded as an example in the matter of expending road funds, and the highways of that commonwealth have gained a wide reputation. For this reason, if for no other, any suggestion as to construction and maintenance methods which may be offered by those who have information relative to the work done by Massachusetts officials must be received with interest by automobile owners and users. The state highway commission has general supervision over the construction of state roads, and it is with respect to these that the greatest attempt has been made to provide that which shall be enduring and economical in maintenance cost. The following discussion is presented

by Phillip P. Sharples, recognized as one of the leading highway authorities in this country:
(By Phillip P. Sharples.)

The state highway commission of Massachusetts has used bituminous binders with a tar base since 1907. A survey of the work done, beginning at Wayland and at Norwood with surface coatings, leads down through a large number of experiments in road construction with varying amounts of binders and various sizes of stone, to the present thorough construction now being practised on the main traffic routes. During the present season a large amount of work has been done on the Worcester-Providence trunk line. Sections have been let in Grafton, Northbridge and at Blackstone. The work at Grafton is typical of this form of construction.

Much attention is given to the preparation of a proper base for the bituminous top proper. Previous work has shown that it is very essential to have a firm, unyielding base, if the top is to endure. Even with the early surface treatments the character of the foundation had much to do with the lasting qualities of the coating. At Norwood, where the base was firm and the macadam road in good condition, the surface coating endures to the present day with only renewals and patching, while at Wayland, where the base was less firm and the macadam in poor condition, the road required constant recoating and was so unsatisfactory that reconstruction work was begun last year.

At Grafton new culverts and new drainage

Dumping Stone for Top Course on Board Platforms.

Spreading Top Course by Hand, and Rolling Sand Base to Insure Even Riding and Even Wearing Road.

work were carefully planned to take care of all surface water and to intercept all underground water where it had a tendency to run from hill-sides underneath the road. The foundation was then levelled off and after rolling with a roller the base course of stone was put on, using four inches of crushed stone (passing a 2.5-inch ring and retained on a .5-inch ring). This course was thoroughly rolled with the steam roller and then bound in with a good binding gravel. After the base was complete it could be favorably compared with an ordinary macadam road. Over this thoroughly built base, a layer of stone passing a 2.5-inch ring and retained on a .5-inch ring was used, making a depth of two inches when rolled.

The use of large stone in the wearing course of the road is an innovation of the last few years in road building, but the results obtained seem to fully bear out the theory. With a water bound macadam it is necessary to fine up the stone on the top in order to get it to stay in place. The

Rolling Wearing Course Preparatory to Tarvia X Coat, the Road Being Rolled Until Surface Is Smooth, Even and Closely Packed.

same, however, is not true of a bituminous bound macadam, since the bituminous binder is able to hold the largest stone in place during the construction of the road and subsequently under traffic. The large stone has the advantage of a better resistance to wear, since it has not already been pulverized by the crusher, and also of transmitting the load to better advantage to the foundation. In using the larger stone, it is essential, however, that the bituminous binder should be so distributed and the subsequent layers of finer stone should be so placed as to insure a thorough bonding of the larger stone.

After the two-inch wearing course has been thoroughly rolled and smoothed out, it is ready for the refined tar binder. The stone used at Grafton was a species of granite, which, under the roller, produced enough fines by breaking up the large stone to lock them thoroughly together.

In the case of a very hard trap rock, it is nec-

Spreading Tarvia X, 1.5 Gallons to the Yard, the Material Being Delivered Hot by Motor Truck and Sprayed by Pressure Furnished by the Roller.

essary to supply a layer of stone crushed to the proper size to hold the larger stone in place and get the desired surface for putting on the binder. A thin layer of stone sized to pass a 1.25-inch screen and to be retained on a .75-inch screen is usually the right size for the purpose.

The refined tar binder was delivered to the Grafton road by the Barrett Manufacturing Company in auto trucks, and on the lower course was of the Tarvia X grade. It was sprayed on through a single atomizing nozzle attached to a single hose under a steam pressure of 20 pounds to a square inch taken from the steam roller. The binder was delivered hot from the works of the company situated at Everett, Mass., 45 miles from the job, and in spite of the distance was always in condition to begin spraying immediately on arrival of the truck.

Great care was taken to spray the binder on evenly and the best possible man on the work was chosen for this purpose. No drainings from the tank at the end of the job were permitted to go on the road and, also, it was made sure that the nozzle was spraying properly before any of the binder was allowed on the road. The result of this careful attention to details is shown in the completed work. The surface is uniform from end to end and the road is of perfect riding quality even in an automobile going at a high speed.

A gallon and a half per square yard of the Tarvia X was used. Workmen followed at once, throwing on a very thin layer of clean pea stone (one-quarter to one-half of an inch). Care was used not to make any very distinct layer of this stone, but enough was applied to thoroughly chink in the surface and to keep the steam roller from sticking. As soon as the tank load of binder

Road Rolled Ready for Seal Coat, Any Excess Pea Stone Being Swept Off.

An example of the use of a Tarvia X seal coat is to be seen on this same road at Blackstone where the Tarvia was delivered in tank cars, heated by a steam boiler alongside of the work and put on from a uniform distributor.

The seal coat on the Grafton work was sprayed on from a pressure distributor attached to the truck. The distributor consists of a rotary pump geared to the driving shaft of the motor and delivers the hot tar to the spray nozzles at a pressure of 35 pounds. The resulting spray is extremely uniform and with the truck at the lowest speed gives approximately one-half of a gallon to the square yard. With the road ready, the truck can spray on 1200 gallons of seal coat in 30 to 40 minutes. Men follow closely behind the sprayer, spreading clean pea stone over the seal coat. The roller follows in order to insure a thorough incorporation of the pea stone in the seal coat. As soon as the roller has finished the road may be opened to traffic without further de-

Putting on Clean Pea Stone Over the Tarvia X, Only Enough Stone Being Used to Chink Up the Surface Soil and Prevent Roller from Sticking.

had been distributed, the roller was put on the road to smooth out the surface and thoroughly consolidate the wearing course.

After this thorough rolling the surface was ready for a seal coat. This was generally delayed for several days until sufficient area had been obtained to take a whole truck load of bituminous material. For the seal coat a Tarvia A grade was used, since experience has shown it to give slightly better results than Tarvia X, which is more generally used for this purpose. Tarvia X is, however, still used when the binder is delivered in tank cars, since it is then difficult to so regulate the work that the two grades can be used at the same time. With motor trucks, however, the combination of the two grades is easily planned for.

Spraying Tarvia A Seal Coat, Half a Gallon to the Square Yard, Delivered by Motor Truck and Sprayed Under Pressure by Rotary Pump Geared to Truck Motor.

lay. This is a great advantage where it is impossible to turn the traffic aside except for short intervals. Roads built under these specifications

Spreading Pea Stone Over Seal Coat—Road Is Rolled Again and Is Then Ready for Traffic.

are showing up exceedingly well with the Massachusetts state road traffic. They are smooth, very agreeable to ride upon, can be used as soon as finished, and give a low cost of upkeep through a long period.

The method of maintenance consists of surface applications of bituminous materials as required. Thinner grades of tar binders have proved very successful for use over tar bound macadam roads. For this purpose thinner grades of refined tars are used, such as Tarvia A and Tarvia B of the Barrett Manufacturing Company. Roads treated in this way show extremely low cost of maintenance and are always in good condition, both in summer and winter. Good examples of this method of maintenance are seen at Westminster, Mass., and at South Walpole, Mass. Both roads were built in 1909, and have required but a single surface coat since the original work was completed. The seal coat was put on at a cost of about eight cents per square yard, making the total maintenance cost per square yard on these roads for a period of four seasons very small.

With the modern type of distributors the costs of surface treatment have been very much reduced, so that the maintenance of this type of road becomes a very easy problem. This method of construction and maintenance also fulfills the new requirements for motor truck traffic. The firm, strong base and the well bound top are capable of upholding the heavy loads imposed by the motor truck, while the surface seems to be proof against all ravelling brought about by

the shear produced by the tractive effort of the driving wheels of the truck.

The wisdom of the recent work with tar binder in Massachusetts is upheld by a comparison with recent work in England. The motor truck problem is much more acute in England than in the United States, since the trucks were earlier in the field and have multiplied much more rapidly in proportion to other traffic on the road. In response to the need, many miles of tar bound macadam have been built in England during the past four or five years. Reports of the condition and behavior on these tar bound roads brought back by delegates returning from the London Road Congress, show that they are standing up admirably under the heavy duty imposed upon them and giving good satisfaction.

BANQUETS PARTS PRODUCERS.

King Motor Car Company Acts as Host at Fellowcraft Club in Detroit.

One hundred representatives of parts makers and firms from which the King Motor Car Company, Detroit, purchases its materials, were entertained at a banquet at the Fellowcraft Club in that city by officials of the company, Jan. 24. The event was announced as another step in the policy of co-operation inaugurated by the King company when it presented its employees with a dividend on wages earned by them during 1913.

Artemas Ward, Jr., president of the company, acted as toastmaster, and among the speakers were the following: T. P. Chase and Luman W. Goodenough of the King company; A. D. Plig-

Completed Road Ready for Traffic, as Presented by the New State Road at Grafton, Mass.

hoff, manager of the J. W. Leavitt Company, San Francisco, and Charles B. Wilson of the Ferro Machine & Foundry Company, Cleveland.

CORRESPONDENCE WITH THE READER.

Six Versus Four Cylinders.

Kindly explain the advantages of the six-cylinder motor. I note by your book that more six-cylinder machines are being made this year than last.

FOUR-CYLINDER OWNER.

Buffalo, N. Y., Jan. 29.

The advantages claimed by the advocates of the six-cylinder motor are: Continuous application of power to the crankshaft of the motor, more perfect balance, absence of vibration, flexibility, hill climbing qualities, economy of operation and upkeep and quietness.

In a single-cylinder, four-cycle motor four strokes of the piston are required to obtain a power impulse. Assuming that the stroke of the cylinder is five inches, the total number of inches travelled to obtain an impulse stroke is 20, and during the operation power is produced for approximately less than five inches, the firing stroke. The balance of the distance travelled by the piston is a loss of energy in that the inertia of the flywheel is utilized to complete the exhaust, intake and compression strokes. In a two-cylinder motor the impulse strokes are separated or spaced, and in a four-cylinder engine there are four strokes, but as will be noted by the diagram at Fig. 1 there are intervals when there is no application of power to the crankshaft of the motor.

With a six-cylinder unit the power strokes overlap; that is, before the piston of the first cylinder has completed its impulse stroke, the charge in the next cylinder to fire is ignited, and this overlapping continues throughout the firing order of the motor.

In a four-cylinder engine the cranks of the crankshaft are set 180 degrees apart; that is, diametrically opposite. Thus in a four-cylinder motor each piston is one complete stroke behind its predecessor. With the four all of the cranks are at dead centre twice on each complete revolution. With the six-cylinder motor not more than two of the six cranks are at dead centre at a time.

Jump Spark Ignition.

Why is it necessary to use a coil with the high-tension system of ignition? Do magnetos have to have a coil? If the voltage of six dry cells is six, what is it when the spark takes place at the spark plug?

NEW OWNER.

Beloit, Wis., Jan. 28.

A coil is used to increase the electromotive force in the secondary circuit, so that it will overcome the resistance at the gap of the spark plug. Air is a non-conductor of electricity and with a space of .03125 inch between the electrodes of

the plug, which is practically a break in the circuit, sufficient energy must be developed for the electricity to jump the gap.

The voltage of six dry cells is approximately six and is not sufficient to overcome the resistance of the air. The resistance to the passage of the current increases with the pressure of the air which surrounds the points of the plug, and with internal combustion engines the spark is utilized to ignite the charge after it has been compressed by the piston, consequently a considerable voltage is necessary.

The actual voltage needed is shown in the chart at Fig. 2, the diagram depicting the electromotive force required to bridge a .02-inch gap with various compressions. At 80 pounds compression it will be noted that over 12,000 volts are necessary to overcome the resistance referred to.

The primary current of the dry cells is trans-

Fig. 1—Diagram Illustrating the Power Strokes of Single and Multi-Cylinder Motors.

formed into a high-tension by an induction coil, which comprises a winding of coarse (primary) wire, and another of fine (secondary) wire. This self-induction, so called, is greatly increased by utilizing a core of soft iron wires around which the windings are placed.

The same principle is employed with magnetos. With the true high-tension types, the armature is wound with coarse and fine wire, and the primary current is transformed into a secondary in the instrument itself.

With low-tension magnetos, also called high-tension, the armature has but a single winding of coarse wire, and the electricity generated is transformed by a separate coil, then led back to the instrument and distributed by it to the spark plugs.

Pitch of Gears and Vernier.

What is the diametral and circular pitch of gears? Will you explain the meaning of pitch terms, also what has the vernier to do with it? I noted use of the words in a book I was reading on trucks.

A. B. T.

Dallas, Tex., Jan. 30.

In the cutting of gears, diameter is always understood to mean the pitch diameter. Dia-

metral pitch is the number of teeth to each inch of the pitch diameter. For example: If a gear has 40 teeth and the pitch diameter is four inches, there are 10 teeth to each inch of the pitch diameter, and the diametral pitch is 10, or, in other words, the gear is 10 diametral pitch.

Circular pitch is the distance from the centre of one tooth to the centre of the next, measured along the pitch line. For example: If the distance from the centre of one tooth to the centre of the next, measuring along the pitch circle, is .5 inch, the gear is .5-inch circular pitch.

For facilitating the measurement of wheels to be sized according to diametral pitch, either Brown & Sharpe No. 61 or 78 steel rules are utilized. The former is a 12-inch member, containing four lines of graduations upon each side, each one as follows: 18ths, 22nds, 24ths, 26ths, 28ths, 30ths and 32nds. Each line of graduations is

Fig. 2—Curve Showing Voltage Required for High-Tension Current to Bridge a .02-Inch Gap with Various Compressions.

figured the whole length of the rule, 10, 20, 30, etc. If a wheel of 60 teeth and of 20 pitch is to be sized, 60 is located on the line of 20ths and that is the pitch diameter of the required wheel. Two of the divisions are added to make the outside diameter, which is 62 20ths.

The No. 78 rule is a 12-inch member, having one inch only of graduations on each end, as follows: Sixths, sevenths, eighths, ninths, 10ths, 11ths, 12ths, 14ths, 16ths, 18ths, 20ths, 22nds, 24ths, 26ths, 28ths, 30ths, 32nds, 34ths, 36ths, 38ths. The intermediate 10 inches are blank, except that the inch lines are made clear across the rule.

Suppose a wheel of 83 teeth is to be sized. Take eight of the blank inches and three of the 10ths graduations, which gives the pitch diameter of the required wheel. Add two of the 10ths, which gives the outside diameter, or 8.5 inches.

The vernier is a device for reading finer divisions on a scale than those by which the scale is

divided. Sixty-fourths are about the finest divisions that can be read accurately by the naked eye. When fine work is necessary, the vernier is employed.

One division of the vernier is equal to .9 of one division on the true scale, consequently the difference equals .1 of the true division, or when each of these is one inch, .1 inch. The difference at the second division is .02, at the third .03, and so on. If the vernier be moved until the third division coincides, it will have moved .03 inch. It is this principle that is applied to measuring instruments.

When graduated to read in thousandths, the true scale is divided into 50 parts to the inch and the vernier graduated into 20 parts, each division of the vernier being equal to nineteen-twentieths of one of the true scale. If the vernier be so moved that the lines at the first division coincide, it will have moved one-twentieth of one-fiftieth, or .001 inch. At Fig. 3 is shown the application of the device, depicting the method of measuring a sprocket tooth. The insert presents the fine divisions somewhat enlarged.

Tungsten Steel and Magnets.

What is the tungsten steel used by magneto makers? Is it superior to regular steel, such as chrome nickel, and is it a combination of alloys or a metal by itself?

INTERESTED READER.

Boston, Jan. 27.

Tungsten as a chemical is a rare element of the chromium group found combined in certain minerals, as wolframite and scheelite, and isolated as a hard, brittle, white or gray metal melting at 2000 degrees centigrade and having a specific gravity of 16.6-19; called also wolfram.

As a metal, steel containing a small amount of tungsten is noted for tenacity and hardness, even under a considerable degree of heat. It is utilized for magnets, since it retains its magnetism longer than ordinary steel. By incorporating simultaneously carbon and tungsten in iron, it is possible to obtain a much harder steel than with carbon alone, without danger of extraordinary brittleness in the cold metal or an increased difficulty in the working of the heated metal.

Graphiting Rims.

On page 55 of the Jan. 10 issue of your book you give a recipe for the care of rims. We are frequently cautioned to avoid the contact of tires with oil. Please state what oil should be used in your recipe, and how can the mixture of oil and graphite be rubbed well into the pores of anything so compact as iron. How much superfluous material should be removed and how much left to produce the high polish referred to. I am quite familiar with the use of powdered graphite and oils as an excellent packing for unions and pipe flanges, and as a lubricant, etc., for screw joints, but I have always left it on the surfaces in considerable quantities, and hardly

see how it will resist water and rust if removed. For the protection of rims I have used shellac. It is fair, but not completely successful. I should be pleased to substitute the graphite treatment, if better, but can hardly reconcile the difficulties named above. H. P. T. Wareham, Mass., Jan. 25.

Ordinary cylinder oil, if not too heavy, can be used in preparing the mixture to which reference is made. As mentioned in the article, enough powdered graphite should be added to the oil until a very thick paste is obtained.

The pores mentioned refer to the surface of the rims, which are not ground and polished. An examination of the rims will reveal tiny depressions or crevices, especially if a magnifying glass be used. These will retain more or less of the mixture even when the surface is well rubbed by a cloth. A combination of oil and graphite used as directed will result in a polished surface, although in the operation it may appear that the greater quantity of the material is removed by the rubbing. The treatment can be improved by sprinkling the rims with dry powdered graphite in addition.

The recipe is based on the actual experience of the writer with rims and tires extending over a period of several years, and he holds that it is superior to the use of shellac for several reasons. The coating of graphite does not increase the diameter of the rim as does shellac, and when fitting a new, cold tire, the shoe slips over the rim easily because of the well known lubricating qualities of the graphite.

The amount of oil used in preparing the mixture is so slight as to be a negligible factor. The writer has carefully noted the shoes used on graphite rims, and, aside from a very slight discoloration, has found the rubber to be in good condition. Another advantage is that a few cents will purchase enough graphite to last for several seasons. It is easily and quickly prepared, and the tires may be replaced as soon as the surplus mixture is removed.

Lighting Dynamos.

Will you kindly advise me if there is any publication on the market dealing with the constructional details regarding automobile lighting dynamos; how to build such a machine for service with a windmill for lighting a house? I would also like to know if you can give me the approximate cost and horsepower of the dynamos of the following lighting systems: Vesta, Berden, Dyalux, Delco, Deaco, K-W, Holtzer-Cabot, Gray & Davis, Apelco, Hartford, Ward Leonard and Wagner. C. F. S.

Allegheny, Penn., Jan. 29.

The constructional details of the various automobile lighting systems are given in "Lighting the Motor Car by Electricity", published by The Automobile Journal Publishing Company.

Regarding the second portion of this question,

the writer does not know of a book which gives complete instructions for the building of lighting dynamos driven by windmill power, but the information could doubtless be obtained from some book dealer. Generators are made by a number of electrical concerns, and it would be cheaper in the end to purchase one than to attempt to build.

The cost of the automobile lighting dynamos referred to varies, as several makers produce different types. They are not rated in horsepower as they generate electricity and require energy to drive or operate them. Electric motor starters, however, have horsepower ratings. Complete information as to the cost of automobile lighting dynamos will be supplied by the makers upon

Fig. 3—Application of Micrometer Tooth Instrument and Vernier for Reading Fine Divisions.

request. The addresses of the makers of the systems named are as follows:

Vesta, Vesta Accumulator Company, 2100 Indiana avenue, Chicago; Berden, Esterline Company, Indianapolis, Ind.; Remy, Remy Electric Company, Anderson, Ind.; Rushmore, Rushmore Dynamo Works, Plainfield, N. J.; Delco, Dayton Engineering Laboratories Company, Dayton, O.; Deaco, Detroit Electric Appliance Company, Detroit; K-W, K-W Ignition Company, Cleveland, O.; Holtzer-Cabot, the Holtzer-Cabot Electric Company, Brookline, Mass.; Gray & Davis, Gray & Davis, Inc., Boston; Apelco, Apple Electric Company, Dayton, O.; Hartford, Hartford Suspension Company, Jersey City, N. J.; Ward Leonard, Ward Leonard Electric Company, Bronxville, N. Y.; Wagner, Wagner Electric Manufacturing Company, St. Louis, Mo.

The Haney Rescue Apparatus Company has been incorporated in Tampa, Fla., with capital of \$2,000,000, to take over the interests of the Haney Fire Apparatus Company of Stockton, Cal. It is planned to locate a \$75,000 factory in Tampa for the production of motor driven fire apparatus and outside fire elevators.

WITH THE CYCLECAR MANUFACTURERS.

Producers Form Association and Adopt Definition—Makes Displayed During the Chicago Automobile Show—Details of New Models Announced Recently.

AT LAST! The American automobile industry has a definition for a cyclecar. It is a motor vehicle having four wheels, propelled by a motor having piston displacement of less than 70 cubic inches and weighing less than 750 pounds.

This definition was evolved by the Cyclecar Manufacturers' National Association, formed during the progress of the Chicago automobile show, which also took steps to define other types of vehicles which have been classed as cyclecars in the past. Of these a four-wheel motor vehicle with motor having piston displacement of 70 to 100 cubic inches and weighing between 750 and

able discussion by all parties concerned, and comprised the first business of the session. A committee, representing the different classes of vehicles covered, was appointed for the purpose of making recommendation, in order that it might be known which concerns were eligible for membership. It would appear that the result was somewhat in the nature of a compromise, since makers of all three classes are represented on the official board, and the movement has been divided into three branches, for cyclecars, light cars and small cars.

The officers of the association are: President, W. H. McIntyre, Imp Cyclecar Company, Auburn, Ind.; vice president, Harry J. Stoops, American Cyclecar Company, Bridgeport, Conn.; treasurer, J. P. LaVigne, LaVigne Cyclecar Company, Detroit; secretary, William B. Stout, Stout Cyclecar Company, Chicago.

AT THE CHICAGO SHOW.

Eight Makes Displayed in the Coliseum and Six Others Outside.

In view of the new definition of a cyclecar, it is a trifle difficult to make comparison between the number of makes on display at the Chicago national automobile show, and the exhibition held in New York City earlier in the month. Disregarding this definition for the moment, there were eight makes at Chicago and six at New York. Six others were displayed at private shows throughout the city.

The eight makes in the Coliseum were divided as follows, under the definitions of the Cyclecar Manufacturers' National Association: Cyclecars, Imp, Mercury, Coey Junior and Kellarkar; light cars, Trumbull, LaVigne and Rex; small car, Car-Nation. Those outside included the following: Cyclecars, Flagler, Steco, Dayton and Zip; light cars, Woods Mobilette and Rayfield.

Of the makes shown in the Coliseum, two were entirely new, not having been announced previous to the opening of the show. The Coey Junior has side-by-side seating with wheelbase of 96 inches and tread of 42. The motor is a twin-cylinder Mack. The concern also offers a coupe model, but as this is equipped with a four-cyl-

Fidella, Announced as a Sister of Bedella of Paris, France.

950 pounds is a light car, and a four-wheel motor vehicle with motor having piston displacement of 100 to 125 cubic inches and weighing between 950 and 1150 pounds is a small car.

It will be noted that these definitions do not take into consideration the matter of wheelbase, tread, seating arrangement or any other factor than the piston displacement and weight. That for cyclecars practically eliminates any but those fitted with two-cylinder engines, with one or two exceptions. Before they are accepted as final they undoubtedly will have to be passed upon by the National Automobile Chamber of Commerce, but it helps some to have a definite working basis.

The definitions were arrived at after consider-

inder, water-cooled motor of larger piston displacement, it comes within the light car classification. The Kellarkar has tandem seating with 36-inch tread. It utilizes an air-cooled motor of the V type, a friction transmission and V belt final drive. In the light car class the Rex is also an entirely new product, and presents a number of distinctive features, included among which is the provision for driving to one front wheel.

DETROIT TO CHICAGO.

Mercury Covers the Distance Over Frozen Roads in Comparatively Good Time.

As was true of the New York show, the Chicago display was made the occasion for at least one overland trip by cyclecar, this being made by H. J. Woodall and Blair Steel in a Mercury, produced by the Mercury Cyclecar Company, Detroit. The journey occupied practically three days, the start being made from Detroit, Thursday, Jan. 22, at 6 in the evening. The party arrived in Chicago at 10 Sunday morning.

Because of the late start it was deemed advisable to make the first night stop at Ypsilanti, about 25 miles from Detroit. The remainder of the 300 miles was through Ann Arbor, Saline, Elkhart and South Bend, with the second night stop at Burton's cross roads, Mich. The third night was spent on the road. The only real delay of the trip was caused through oiling difficulties, due largely to the cold.

FIDELIA OF CLEVELAND.

New Model Is Introduced as a Sister of Bedelia of Paris, France.

During the recent automobile show in Cleveland, O., the J. H. Sizelan Company of 61 Penrose street, that city, revealed a new cyclecar, termed the Fidelity, which was introduced as a sister of Bedelia, the name applied to the first cyclecar produced in Paris, France. This machine is designed to seat two passengers tandem, and has a wheelbase of 96 inches, tread of 38 inches and weight of about 425 pounds.

The motor is a two-cylinder DeLuxe, V type, rated by the maker at 10-12 horsepower, with piston displacement of 70.69 cubic inches. Cooling

is by air, utilizing the customary fan. Ignition is by Bosch magneto and the carburetor is a Schebler. The entire power plant is assembled as a unit and is suspended at three points under a hood of distinctive design. The 10-gallon fuel tank is located in the cowl dash, and a separate oil tank, holding one gallon, is placed directly in front of the dash under the hood.

A friction transmission is employed, this being arranged to afford three forward speeds and reverse. Final drive is by two 28-degree V block belts. Provision for braking is made by the use of external contracting blocks acting on the rear pulleys. Steering is accomplished by the conventional automobile knuckle and tierod to a special ball crank connected to the steering column and front wheels.

Full cantilever springs are employed front and rear, these being the product of the Perfection Spring Company of Cleveland. The wheels

Side View of Fidelity Model, Showing Belt Drive, Rear Spring Suspension and Carriage Type of Steps.

are of wire, fitted with 28 by three-inch tires. The road clearance is 9.5 inches. The passengers are provided with special hammock seats, and the whole design is with the idea of presenting a low centre of gravity, the seats being only 17 inches from the ground.

The body is described as a torpedo boat type, full streamline, and is accessible by steps on the side similar to carriage practise. The equipment includes a complete electric system, consisting of a 24 candlepower headlight, two six candlepower side lights and a four candlepower tail lamp, all of special design, and an electric horn.

The Ward Cyclecar Company, Milwaukee, Wis., makes announcement of the Ward, utilizing a Mack motor, friction transmission and V belt drive. The wire wheels carry 28 by three-inch tires. The body seats two side by side. The wheelbase is 96 inches and the tread 41.

COMET IN TWO BODY DESIGNS.

Indianapolis Maker Presents Pleasure and Delivery Vehicle on Same Chassis.

The Comet Cyclecar Company, Indianapolis, Ind., announces two body designs fitted to the same chassis, one of which is designated as model A, a two-passenger tandem machine with 100-inch wheelbase and 36-inch tread, and the other as model C, a delivery wagon of 300 pounds capacity. The company has been experimenting with this chassis for the past year, and believes it has perfected a design which will prove satisfactory in every respect.

The motor is a DeLuxe two-cylinder unit, with bore of 3.5 inches and stroke of 3.67, rated by the maker at 9-15 horsepower. Ignition is by the Atwater Kent Unisparker system with automatic spark advance. Gasoline is fed by grav-

Note the Low Hung Appearance of the Comet Seating Arrangement, and the Attractive Body Lines.

ity from a three-gallon tank located under the cowl to the latest type of Schebler carburetor. Cooling is by air, the circulation being assisted by a two-bladed aeroplane type aluminum fan mounted on a ball bearing shaft driven by a belt from the crankshaft. The motor is enclosed by a removable hood with large louvers in the side and a screen in front.

The transmission is of the planetary type, and is located under the front seat. This affords two speeds forward and reverse and is operated by two hand levers and a pedal. The clutch is of the expanding ring type. Final drive is by two 1.125-inch V belts. The rear axle is suspended through links to the ends of the rear springs and can be shifted backward or forward, to accommodate the belts, through an adjustable torque rod arrangement. The front axle is tubular, with drop forged yokes brazed on either end and drop forged knuckles for the front wheels. Radius

rods are attached at each end of the axle inwardly to the frame through a ball joint connection.

The front spring is a semi-elliptic transverse member, 1.5 inches wide and 25.25 inches long, crossed over the front axle with the body suspended at the centre. The rear springs are quarter-elliptic, 28.5 inches long and attached to the body by substantial brackets. The steering gear is of the pinion and quadrant type, operating through a drag link to the steering knuckle on the front axle. The brakes are internal expanding on the rear wheels, the bands being three inches in diameter, and are supplemented by the transmission in reverse for emergency. The wheels are of wire, fitted with 28 by three-inch tires.

The frame is of four by one-inch second growth ash, and is built separate from the body, so that the two bodies supplied may be interchangeable if desired. The corners of the frame

are reinforced with steel angles. The pleasure car body is 23 inches wide, and it is maintained that it supplies ample leg room and storage capacity. It is made readily accessible by doors front and rear. The road clearance is 10 inches, and the weight about 650 pounds. The equip-

ment includes a complete gas lighting system, repair kit, pump, etc., and a top, windshield and speedometers are furnished as extras.

The company is composed of old manufacturing men, including E. R. and S. C. Parry of the Parry Manufacturing Company, and Marshall T. Levey of the Thornton-Levey Company, both concerns being located in Indianapolis. Fred P. Mertz is engineer. The factory is located at the corner of 10th and Canal streets, and it is stated that deliveries already are being made.

NEW CYCLECAR MODELS.

Brief Constructional Details Regarding Latest Designs Announced Recently.

M. C. Whitmore, Dayton, O., is working on the Arrow cyclecar, which is to be presented with

two types of bodies, one for two passengers seated tandem and the other for delivery purposes. The wheelbase is 100 inches and the tread 36. The motor is a DeLuxe two-cylinder, with Bosch ignition and Schebler carburetor. The transmission is of the planetary type, affording two speeds forward and reverse. Drive is by shaft and bevel gearing to a semi-floating rear axle. Wheels are of wire, fitted with 28 by three-inch tires.

T. E. Buckles, Manchester, Okla., is experimenting with a design which will seat two persons side by side. The wheelbase is 96 inches and the tread 36. The motor is a DeLuxe two-cylinder, with Bosch magneto and Schebler carburetor. The Buckles will utilize a friction transmission, with V belt drive. The wheels are of steel and will carry 26 by 2.5-inch tires.

The Continental Engine Manufacturing Company, Milwaukee, Wis., has been experimenting upon a Continental cyclecar, which is to be produced in both pleasure car and delivery wagon types. The two passengers are seated tandem. The wheelbase is 96 inches and tread 32. The motor is of the firm's own design, being a four-cylinder, air-cooled unit, with bore of 2.68 inches and stroke of 2.93. The cylinders are of the T head type, cast separately, and lubrication is either by circulation or non-circulating splash, as purchaser desires. An option also is offered in the matter of ignition, either a Bosch or an Eisemann magneto being utilized upon order. The carburetor is a Schebler. The machine employs a friction transmission, and final drive is by either chain or belt. The wheels are of wire, with 30 by three-inch tires.

William B. Engler, Pontiac, Mich., is announcing the Engler, a tandem seating cyclecar with 110-inch wheelbase and tread of 36 inches. The motor is a V type, air-cooled, rated by the maker at 10 horsepower. The transmission is friction, final drive being by V belts. The rear spring suspension is of the cantilever type. The wire wheels are equipped with 28 by three-inch tires.

The Warren Electric & Machine Company, Indianapolis, Ind., presents the Hoosier, which is said to be built somewhat along the lines of a racer and with good wind resisting lines. The wheelbase is 96 inches and the tread 36. The motor is a DeLuxe; transmission, friction, and final drive, V belt. It is understood that this machine will be offered with both tandem and side-by-side seating.

The Northwestern Motorcycle Works is still another Chicago concern to produce a cyclecar, this being known as the Logan. It utilizes a DeLuxe motor, equipped with Atwater Kent ignition; a friction transmission and final drive by V belts. The wheelbase is 92 inches and the tread 40. The two passengers are seated by side by side.

The Keller Cyclecar Company, Chicago, is one of the latest to announce a cyclecar from that city. The Keller will seat two persons

How the Comet Cyclecar Company Seeks to Solve the Package Delivery Problem.

tandem, the wheelbase being 96 inches and the tread 36. The motor is a two-cylinder, air-cooled Wilson, with bore of 3.5 inches and stroke of 3.62 inches. Ignition is by the Atwater Kent Unisparker system. The machine will employ a friction transmission, with final drive by V belts.

The Ideal Shop, Buffalo, N. Y., goes one step further than other concerns by offering three options in the seating arrangement. The Ideal will be produced either for one or two passengers. In the latter type, the two persons may be seated tandem or side by side, at the option of the purchaser. The wheelbase is given as 96 inches and the tread as 36. The motor is a DeLuxe; transmission, planetary, and final drive by belt from the countershaft to rear wheels. The wire wheels will be fitted with 28 by 2.5-inch tires.

ANALYZES BALL AND ROLLER BEARINGS.

Part II—Professor Goodman of Leeds University, England, Discusses Various Types of Ball Bearings and Gives Formula for Calculating Maximum Workings.

IN HIS lecture before the Institution of Automobile Engineers, London, England, Prof. Goodman of Leeds University described and illustrated the results of his experience and tests with roller bearings, which report was published in the Jan. 25th issue of The Automobile Journal. The second part of Prof. Goodman's lecture dealt with ball bearings, in the modern type of which he said there was no end thrust at all, and no end thrust troubles. The friction was held to be very much less than in the majority of roller bearings, hence, there was a great deal to be said in their favor. The report concerning ball bearings follows:

Engineers would say, stated Prof. Goodman, that "the ball bearing only bears upon a point, while the roller bears on a line. Hence the ball bearing of a certain size

Fig. 5—Various Types of Ball Bearings—Those in the Top Row Are Journal Bearings and in the Bottom Thrust Bearings.

cannot possibly carry so high a load as a roller bearing of the same size."

There was an element of truth in that, but it was not the whole truth. If one had equally good material in rollers as in balls, and if one could be certain of getting no end thrust on roller bearings, that argument would hold rigidly, but since end thrust did come in, and since other troubles came in as a matter of fact in practise, the ball bearing with one exception was able to carry a much bigger load than any roller bearing.

He then illustrated and described the testing machine in which the roller and ball bearings were tested, and said it was of some interest, inasmuch as it was the only testing machine in which the load could be applied by lever. The machine was driven by an electric motor, and enabled a very high range of speed to be obtained. It would test loads up to 10 tons and give speeds up to 3000 revolutions a minute, or down to five or six revolutions a minute when required. The next slide showed the different types of ball bearings that had been used since their first application to machinery. Probably the earliest type was one having a steel sleeve with either a V or a rounded groove in the sleeve and the outer casing fitted with two conical rings.

The casing itself was tapped, and the rings were screwed on the outer edge, the idea of that being to al-

low the bearing to be adjusted. Nearly all the early makers aimed at making their bearings adjustable, and it was a great blunder. A little thought would show that that was so. With a heavy load on the top of the bearing and the upper part of the cones remaining stationary, the cones would get worn into a ridge. Then when the conical rim was rotated in order to take up the wear, a different part of the ring was brought into contact with the ball, and it ran partly on the old ridge and partly on the new portion. The ridge of the ring was no longer perfectly central. The ring was no longer circular at the part where the ball rolled, with the result that it was impossible to get anything like accurate adjustment for a bearing of that type.

The next type of bearing was made with a flat sleeve and cones, practically the same as the previous one, but the next arrangement was one where the sleeve itself was screwed on the shaft and the outer portion of the stationary part was made either plain or rounded. With that one could get much better adjustment, because the ring was always rotating and wore fairly evenly. Although the adjustment was not perfect, and the arrangement not altogether satisfactory, it was a great deal better than the previous one. There was something to keep the balls in position.

Bearings with Grooved Races.

Then the latest of all was a ball bearing with grooved races. The earlier grooved races were made with the radius of the groove equal to the diameter of the ball, or the radius of the groove twice the radius of the ball. The modern practise was to use a very much smaller radius than that, somewhere in the neighborhood of .5625 or .625 of the radius of the ball—the reason for that would be seen later—or else end thrust bearings were made with grooves of 45 degrees. They were, however, found to be anything but satisfactory. The balls ground and became very much crunched during the running of one of the early tests that he made of balls of 1.25-inch diameter. When they came out they looked like golf balls that had been badly used—very badly scratched.

The next improvement, or attempted improvement, was to make the races unsymmetrical at 40 degrees, but there was bound to be grinding with these unsymmetrical races, as they rotated at a higher speed in one part than in another. The races were so made that the ball would have a true rolling motion, similar to a conical bearing with a conical roller. That was a great deal better than the other, but still quite unsatisfactory in running.

Effect of Friction and Loads.

During several of the tests that he made of bearings of this type the grooves were ground to the greatest possible degree. Notwithstanding the accuracy and care taken in manufacture, he always found that the bearing heated up at first, but after it had been running it would settle down and the friction would fall to a minimum. Then, curiously enough, if the load were increased or decreased, friction invariably went up and heating occurred. He thought the reason for that was that the different loads so altered the shape of the races as to cause them to be unsuitable for the balls until after they had been running for two or three days, when they became properly bedded again. When the loads were altered the races sprang a little, and were no longer properly bedded, but after two days they would get all right again. It was anything but a satisfactory bearing, although friction was certainly lower and the balls lasted longer.

The next type was where a single V was used and a flat surface. That was better, but not satisfactory. Then the next type of bearing was that with perfectly plain rings and cages to hold the balls. They ran perfectly and gave not the slightest trouble. The balls improved with wear—improved with use—and the friction was in the neighborhood of one-third of the friction of the best

that had preceded it, and it ran in a highly satisfactory manner. Then as an improvement on that was the grooved race. The friction on these grooved races was always slightly higher than the friction on flat races, but the great advantage of the grooved races was that they would carry about two to 2.5 times the load that the flat races would carry. Even at the present time for certain purposes the flat race bearing was better than the grooved, but if one was certain of keeping the shaft and the race in line with their housings, then the grooved race was the better.

One of the earlier type of bicycle ball bearings was shown, having its races unsymmetrical and so arranged as to get a thoroughly rotary motion for the ball. This, however, was not altogether a success. Another was a three-point bearing, with the three points on the surface of the cones. It was fairly well used, but not altogether satisfactory. There was another type of bearing with grooved races and a cage to hold the balls in position on the hemispherical seating of the outer ring.

The lecturer went on to say that he had already spoken about adjustment, or, rather, the futile attempts that had been made at adjustment. The next point was to look at the workmanship in so far as ordinary two-point bearings with flat races were concerned.

Early Types of Bearings.

As regards workmanship in the early days of ball bearings, 25 or 30 years ago, bearings gave a great deal of trouble. The reason for that was very largely due to the fact that the balls and the races were not made with a sufficient degree of accuracy. If there was one thing brought out of late years above all others, it was the importance of accuracy in manufacture, and the ball bearings of today could never be made a commercial success except for automatic machinery for turning out the balls and races of a very high degree of accuracy. As showing the importance of getting accurate results, he had plotted a diagram, Fig. 7, showing the stresses that balls take. For example, it was shown that a .5-inch diameter ball with a load suitable for a slow running bearing showed a deflection of .0015 inch.

When two flat plates approached one another loaded and having a ball between them, if the ball was a thousandth of an inch out of truth there was 200 pounds extra load upon the ball. Suppose they had a thrust bearing and one of the balls was a thousandth of an inch larger than the rest, that ball would have 200 pounds or thereabouts more to bear than the others. The total load that might be put on a half-inch ball running at very low speeds was somewhere in the neighborhood of 300 pounds. Hence an error of one-thousandth of an inch in the diameter of the ball or one-thousandth of an inch error in the races would put somewhere about 200 to 300 pounds extra load on the ball, with the result of certain failure. With an inch ball a safe load was somewhere about 1000 pounds, and the effect of a thousandth of an inch error was to put an additional load of something like 800 pounds on the ball; similarly, with a 1.5-inch diameter ball in like proportion.

Adjustable Types.

With higher speeds the several loads would be very much reduced. That was to say, they could only work at somewhere about half loads. Hence, with fast running of a bearing it was of vastly more importance to get extreme accuracy in workmanship than with slow running bearings. It would be seen that a thousandth of an inch error in the dimensions of the balls, or a similar error in the races, was absolutely fatal to the bearing. In the bearing where adjustment was obtained by screwing up one of the cones it would be seen that if the bearing were worn to the extent of a thousandth of an inch it would be simply ruined at once by attempting to adjust it, because the race would be out of truth to the extent possibly of two or three-thousandths of an inch. Hence, anything in the shape of adjustment was quite out of the question.

He had already spoken of the slipping of rollers. Similarly in ball bearings there was always slip between the balls and the sleeve. It was a perfectly simple matter to prove that the speed of rotation of the cage itself was one-half of the speed of the shaft. Very light counters were attached, one to the shaft and one to the cage. Then the bearing was allowed to run under various loads for considerable periods, and the difference between the counters showed the amount of slip in the balls on the shaft. It was found from that that the

amount of slipping depended very largely upon the load.

A good many makers in the early days would say, though they would not think of making the statement now, "What does it matter if the balls are not all exactly of the same size to start with? Suppose some of the balls are as much as ten-thousandths of an inch bigger than their neighbors, after they had been running for a short time the larger balls will wear more than the smaller ones, and after a few days' running they will be approximately the same size and work as smoothly as the others."

Varying Diameter of Balls.

This was entirely fallacious, for this reason: The balls themselves were invariably carried in a cage, in which the large balls would get a larger proportion of the load than the small balls. Hence there would be more slip with the large balls than with the small ones. Hence the speeds at which they would tend to run would differ; but they could not differ, because the cage prevented that. Either the large or the small balls must slip, and it stood to reason that the balls which would slip were the balls with the smallest load upon them. Hence the small balls slipped and got cut up, scratched and damaged, whereas the large balls remained perfect, and exactly the reverse action occurred to that which some-makers in days gone by urged would happen. It was therefore of vital importance to get the balls all of exactly the same size as nearly as possible. All the best makers today would produce balls which they guaranteed to within one ten-thousandth of an inch of their proper sizes. There were, however, second class balls sold which were slightly above or below the standard. It did not matter one fig so long as all the balls were of one size in the bearing; they might deviate from the standard either above or below, but to mix second class balls indiscriminately would lead to a hopeless mess, and failure was certain to occur.

Some chassis makers fell into that mistake, thus accounting to a large extent for some of the troubles they experienced with regard

to wear of bearings. The wear on properly made ball bearings was practically nil. The balls wore to an extremely small amount in the early tests that he carried out at the loads and speeds adopted. He would run a bearing under a given load for perhaps 1,000,000 or 5,000,000 revolutions of the shaft. The balls were very accurately measured in a Whitworth measuring machine before and after with the object of finding the amount of wear. The greatest possible care was taken in the measurements, but sometimes he found that the second measurement showed the balls to be a shade bigger than before the test was carried out. That was undoubtedly due to errors in measurement. They were measured to the hundred-thousandths of an inch. One of his colleagues in the chemical department of the Leeds University offered to weigh the balls in a chemical balance. He (the lecturer) was quite hopeful, but even then in some instances the weights given after the tests were greater than before, evidently again due to errors in measurement. The methods were nothing like accurate enough.

Effect of Overloads.

Then came the question how to tell whether a ball was overloaded or not. He then hit upon the method of examining the balls under a microscope. If a ball was not overloaded, when examined under the microscope it would improve in appearance. A new ball straight from

Fig. 6—Chart Showing the Greater Starting Effort in the Case of Plain White Metal Bearings as Compared with Ball Bearings.

the makers when examined under the microscope exhibited slight defects, but after it had been running a few weeks under a moderate load the surface materially improved, but if it were overloaded it appeared to be covered with tiny flakes of snow all over; the flakes were really tiny crystals which had broken away from the surface of the ball. When these specks appeared on a ball they could not be detected at all with an ordinary lens; it was necessary to work to 300 or 400 diameters of magnification. It was found that as soon as these specks occurred the ball would go wrong if continued under test at the same load.

The way in which they failed was interesting. With all the tests he had made, running over 15 years, he had only had about half a dozen balls actually break in the testing machine. Nearly all the failures—practically all—were due to the peeling of the ball. The surface of the ball peeled away like the peel of an orange. It was a most curious phenomenon that he had not yet fathomed. They nearly always peeled on one hemisphere and not on the other. He had scores which had peeled on one of the hemispheres, and could discover no reason why one-half of the ball should fail and the other half should not. It was an extremely interesting problem.

Hardening and Grinding Races.

In the rings and the races of the ball bearings it was extremely important to have simple cylindrical rings. In the early days he and many makers—he spoke of himself as testing the bearings—made the mistake of

Fig. 7—Diagram Showing the Stresses That Balls Take.

having holes drilled in the races in order to attach the race to the shaft and to hold the races of the bearings themselves. Holes were drilled while the metal was in its soft state, and then hardened and ground. Invariably the races failed where the hole occurred. For certain purposes they had races made with a slight projection or lug upon them, and in every case these failed at the lug. A good many tests had been made, all pointing to the fact that for reliable ball bearings it was necessary to stick to the cylindrical form of ring and not have any grooves if they could possibly be avoided. He knew some makers would not agree with him, but he had conducted a great many tests, and he knew where the bearings all failed; it was where they departed from the circular form of ring. One interesting point in this connection was that in some of the early tests the inner ring was made somewhat longer, and two holes were drilled through it, and set screws were put through it into the shaft—screwed into the shaft in order to hold it in position. As soon as any load was put on the bearing the set screws or the pins in some instances sheared off immediately. He could not understand it. The coefficient of friction was a thousand, and the load on the bearing was known. It was a perfectly simple matter to find what the shearing stresses on the pin were, and he could not account for the breakage. It occurred to him that the coefficient of friction to be reckoned with was not the coefficient between the ball and the race, but the static coefficient between the shaft and the race. Assume that the race was a little bit big-

ger than the shaft, then as the shaft rotated one portion of the ring was stationary with regard to the shaft. The coefficient of friction to take into account for determining the load on that point was the static coefficient, which was somewhere in the neighborhood of one-third instead of one-thousandth, with the result that if one had a 1000-pound load on the bearing one might get 300 pounds shearing stresses on the pin. Looking at it in that light entirely accounted for the shearing of the pin.

Then he followed the usual method of attaching the sleeve to the shaft in the tests he made at first. He had the sleeve made slightly tapered, and screwed the shaft to it. A nut on it tightened it up. That answered fairly well except under the heaviest loads. Then one of the makers for whom he was working at the time suggested an adapter—usually a cone metal adapter. The bearing was made slightly tapered, and the ring was made taper, and the split adapter was put in. Then the nuts were tightened up, and drew the adapter into the bearing, and caused it to grip the shaft. That made quite a good arrangement for moderate loads; for fairly big loads it was not altogether satisfactory. The best way was either to shrink the inner ring onto the shaft or to force it on with a little hydraulic press; but one could easily do mischief. To allow too much would expand the ring to such an extent that it would jam the bearing. It must be remembered that they were working to ten-thousandths of an inch. There was extremely little shake, so that if the inner ring were expanded by one or two ten-thousandths of an inch the whole bearing would be jammed, and would have a very much bigger load put upon it than was intended. Many a bearing had failed through that. The safe way of getting the shrinkage was to make a rule that the shrinkage must not be more than one or two ten-thousandths of the diameter of the shaft. Or what was perhaps a more practicable way of dealing with it was to heat the inner ring in a bath of oil at about 150 degrees Fahrenheit. If it would not slip on too much shrinkage had been allowed, and if it slipped on too easily too little shrinkage was allowed. It ought just to slip on fairly freely, and it was better to have it a little too slack than too tight on the shaft.

Retaining Balls in Cages.

That shearing of the pins was quite an interesting point. On this type of bearing with perfectly plain rings, not grooved, one could readily get in the full number of balls. It was an old fashioned dodge, but a perfectly simple matter to pack in the full number of balls and slip in the cage in halves, but with a grooved cage some other method must be used to get the full number of balls in. What was usually done was that the ring was pulled to one side so that just over half the full number of balls could be packed in. Then they were evenly spliced and the spring cages were put in, or the ordinary solid cage, which was more commonly used at the present day, but one could only get slightly over one-half of the full number of balls into the bearing. In order to get more balls in the races were often grooved at the side and the balls forced in. As many as possible were inserted by the method first described and the others were forced in with a copper hammer, or were sprung in. These rings were liable to "go" just where the groove was made. This groove was filled in before the bearing was hardened; it was not now made quite so deep as formerly. In some of the earlier bearings a loose piece was fitted into the groove, or it was made the same depth as the race and the race fitted in. The race now was filed away so that it was not quite so deep and the balls were forced in.

In the Skefko bearing the balls could be got in quite readily. There were two suitable grooves on the main ring of the bearing. The whole ring could be fitted to one side and the balls could be slipped in. Besides getting in the full number of balls it was a great advantage, as a shaft which was very much out of truth would run perfectly. He had carried out tests with intentionally bent shafts to show the effect of that peculiarity. In the case of motor cars where the frame springs considerably that type of bearing lent itself very well to the requirements of the case.

Multiple Ring Bearings.

When a very big load was wanted to be taken on a thrust bearing, defects arose. One could not always get a sufficient number of balls in to carry the load. Therefore a bearing had been brought out, having a large number of balls in a cage with very big flat collars and race, but it was altogether a failure, for the simple rea-

son that the collars deflected under the load and the inner balls received more than their fair share of the load and very quickly peeled. The little flakes from the inner balls got in amongst the outer balls, and the whole bearing, when under test, went to pieces in a very few hours. He had never got good results with that bearing.

His own opinion was that the best thing to do when one wanted to use a multiple ring bearing was to make a flexible bearing. In this particular case standard types of bearings were used. Inside the case itself, but outside the rings, a piece of linoleum was put. If there were any tendency to unequal loading this linoleum would "give", and it fairly distributed the load over every ring. There was also less spring in the shaft. There was always some amount of spring in the shaft, causing the outer rings to get more of the load than the inner ones. If the spring were excessive trouble ensued, but by inserting a linoleum liner trouble was entirely avoided. In addition, it was as well to make a spherical seat, so that if the shaft got out of line it automatically adjusted itself, as was done in many ordinary types of bearings. The same thing could be done for thrust bearings. The standard types of thrust rings with heavy cast iron housing could have a piece of linoleum put below it. The spherical seat was also treated in the same way to allow for the maker making it slightly out of truth with its housing.

Excluding Foreign Elements.

In order to exclude dust a sheet iron ring was put round and a small groove made and filled in with oil. It was just as important to keep a ball bearing free from dust as it was to keep an ordinary bearing free from dust. People did not always realize that. Consequently, many bearings, otherwise excellent, went wrong from dust getting into them.

The lecturer then threw on the screen a diagram, Fig. 6, showing a comparison between the friction of an ordinary ball bearing and a bearing of white metal after running for a short time. The load was the same in each case, and the coefficient of friction was stated, while both were running with ordinary lubrication. It would be seen that the effort required to start the white metal or gun metal bearing was enormously greater than that required after running for a time. With the ball bearing the reverse was the case; sometimes it went up, and sometimes it did not. This was an extremely important point in dealing with machinery that was stopped and started very frequently. The white metal bearing with bath lubrication showed an improvement upon the diagram, but in all cases the coefficient of friction of well made ball bearings was considerably lower than that of a shaft running in a bath of oil.

Cost of Production.

In regard to the question of cost, a ball bearing always costs more than an ordinary bearing, but in some cases the total cost of a machine was actually less with ball bearings than with ordinary bearings. Take the case of an electric motor or dynamo. With ball bearings it was possible to have a short bearing 1.5 inches long as against a bearing 15 to 18 inches long if ordinary bearings were used. This meant that the shaft could be shortened, with a corresponding shortening of other parts, with the result that many makers now quoted lower prices for machines with ball bearings than for machines fitted with ordinary plain bearings.

Then it should be remembered that a ball bearing required practically no lubrication—once in two or three months perhaps, simply and solely to prevent rust. If rust could be prevented by any other means a ball bearing would run just as well without oil as with oil. He knew there was a difference of opinion on this point, but he thought he had had sufficient experience to enable him to state definitely that such was the case. It was necessary to be extremely careful about oil. A ball bearing could be easily ruined in a few days or weeks by the use of improper oil, which was likely to set up corrosion. There were certain oils on the market which were quite good. Some time ago he was told that the best qualities of lard oil were probably the best, on the whole, for ball bearings. At any rate, he knew of cases in which bearings had been absolutely ruined by the use of improper oil.

Advantages of Ball Types.

In conclusion, he would say that, with a shafting fitted with ball bearings—properly made ball bearings—it was possible to transmit power more economically than by any other means known. Electrical men might prick

up their ears at that statement, but it was quite easy to transmit power much more efficiently with shafting mounted on ball bearings than electrically. He was quite willing to admit that the electric method, under some conditions, was the more convenient method, but where the conditions were simple then with a shaft mounted on ball bearings very high efficiency indeed could be obtained. Although a great deal of work had been done on the question of ball and roller bearings, there was yet a great deal more to be done, and he hoped in the near future some one would be able to take up this subject and deal with it more thoroughly than he had been able to deal with it.

Perhaps it would be interesting, before closing, to give a formula for calculating the maximum working

load on a ball bearing. The formula was $\frac{K m d^3}{N D + C d}$ where

m = the number of balls in the bearing.

d = diameter of the balls in inches.

N = revolutions a minute.

D = diameter of ball race, diameter being taken from the point of contact of the ball with the race, or for a thrust bearing D = the diameter taken from the centres of the balls.

The constants C and K are as follows:

For Thrust Bearings.

	C	K	
Flat races 200		500,000	when the radius of the race is about twice that of the ball.
Hollow races 200	from 1,000,000		to 1,250,000 when the radius of the race is .5625 that of the ball.

For Journal Bearings.

	C	K	
Flat races 2,000		1,000,000	where the radius of the race is about twice that of the ball.
Hollow races 2,000	from 2,000,000		to 2,500,000 where the radius of the race is about .5625 that of the ball.

Some makers' lists gave higher loads than that formula gave, but all he could say was that whoever worked to the formula he had given would not have trouble. He was not prepared to say that if they worked to some makers' lists they would not have trouble. Some lists were very much too high. He knew that from actual tests of their bearings, and he knew that if they worked from his formula they would be safe.

Formula for Calculating Loads.

A number of questions were asked upon points contained in the lecture. One of these had reference to the way in which D in the formula was measured. Prof. Goodman said he had many shots at that formula before he could get it into a satisfactory form. Sturtevant, who had worked in Germany, published an expression 10 or 12 years ago, in which the speed of the shaft did not come in at all. From the very earliest experiments he (Prof. Goodman) made he found that the speed of the shaft was most important, and the first attempt at getting at an expression for a safe load for a bearing was purely in terms of speed of the shaft. He found, however, that there was a weak spot in it. To get at the result desired he had a series of collars threaded on to a shaft, and in all cases the same number of balls were used with the same load on every bearing, but the diameters of the ball races were different. It was always found that the balls on the biggest diameter of ball race failed first, and then those on the next biggest, and so on, clearly proving that it was the speed of the ball itself and not the rotations of the shaft that was the most important point. Thus he introduced D . It was purely an empirical formula, but it had a theoretical basis. After carrying out a very large number of tests on different bearings the difficulty was to bring them all into line. After plotting some hundreds of tests it was found that a curve could be drawn which very nearly fitted the results. That curve, which was published in the proceedings of the Institution of Civil Engineers, represented many years of work.

He described how he had designed an adjustable ball bearing, which had proved quite satisfactory. On a shaft he put three ordinary ball bearings side by side,

and provided the middle one with a fine threaded screw which could be tightened to make the necessary adjustment. In unskillful hands, however, the bearing might be ruined in five minutes. In further reference to the radius of the ball race, he said the first tests were made on a flat race, i. e., one of infinite radius. Then a series of tests were made on grooves twice the radius of the balls, and he gradually worked down until the last series of tests were made on a groove .5625 the diameter of ball. He invariably found that as the radius of the groove went down, or the better the groove fitted the ball, the higher was the load carrying capacity, but the higher also was the friction. There was no question about that. The lowest friction of all was obtained with per-

fectly flat or perfectly cylindrical surfaces, as the case might be, but, as before stated, the load carrying capacity was smaller. The investigations of others have also shown that the closer the fit between the groove and the ball the higher was the load carrying capacity on the bearing, but that there was more friction. The load carrying capacity of a bearing varied as the square of the diameter of the balls when the speed was constant. That was approximately, though not rigidly, true. It applied to balls of about one inch in diameter. Balls of four inches diameter, for example, would not carry twice as much load as balls of two inches diameter, because the four-inch balls would not be hardened, proportionately to their size, to so great a depth as the smaller ones.

AN ENTHUSIASTIC MOTORIST.

Bought His First Machine in 1899 and Has Driven 225,000 Miles Since Then.

C. M. Kimball of Winthrop, Mass., purchased his first automobile, a steamer, in 1899, and has purchased 18 cars since then. In the 14 years he has driven automobiles 225,000 miles.

He was one of the first to become interested in the Stutz machine, when it was first put on the market by the Ideal Motor Car Company, now the Stutz Motor Car Company, of Indianapolis, in 1912. He has purchased a car of that make each year since and recently took possession of his 1914 Stutz Bearcat model. He says:

In the two years I have been driving Stutz cars, I have covered about 25,000 miles, and am very happy to say that I have not had any mechanical trouble; have never met with any kind of an accident, and have driven one of these machines 5000 miles without a puncture. On one set of tires I got a mileage of 8000.

Recently, I left Winthrop for Portland, Me., starting at 10 in the morning, and returned the same day, arriving in Winthrop at 6 in the evening, and covering about 230 miles. On this trip, as on most of my trips, I managed to get 15 miles to the gallon of gasoline.

OAKLAND WINS IN URUGUAY.

Two of the Three Cars to Finish in Annual South American Classic.

The Oakland Motor Car Company, Pontiac, Mich., is in receipt of a cablegram from Johnson Martin, manager of the Oakland branch in Montevideo, Uruguay, stating that two Oakland cars finished in their respective classes in the annual Montevideo cross country race held last month. The cablegram bears date of Jan. 28, and reads as follows:

In the Montevideo cross country race, Oakland model 43 wins first place in class A. In class B Oakland 6-60 second. Owing to terrific strain put upon entries only three cars finished.

This race is the annual South American classic, and the course is from Montevideo, on the coast, to the town of Salto, in the northern part of the republic. It is a non-stop contest, covering approximately 400 miles, and the cars are

driven day and night. Two of the principal rivers, Santa Lucia and the Rio Negro, and a number of smaller streams are crossed, some by ferry and others by means of fords.

This is not the first time the Oakland has been successful in South American events. It finished second in the 1913 race over the same course, and was first in the recent Rosario race in Argentina.

HOW TO GET TIRE MILEAGE.

Goodyear User Makes Some Interesting Suggestions for Motor Car Owners.

Dr. Thomas Hubbard, Toledo, O., has obtained 10,000 miles from the Goodyear tires on the rear wheels of his car, and his front Goodyears already have been run 13,000 miles and are still in fair condition. In a recent letter to the maker, the Goodyear Tire & Rubber Company, Akron, O., Dr. Hubbard offered the following summary of "the essentials of conservation of tires" as developed by his experience:

1—Uniform inflation, depending upon the load carried. Average, 60 to 65 pounds front, and 70 to 75 rear, for car 2300 to 2400 pounds, properly tired.

2—Test tires every three days. Discard an inner tube that leaks enough to lower pressure 15 pounds or more in less than three days.

3—Drive car steady and true. Slewing and skidding are evidences of bad driving, just as much as allowing a horse to stumble or fall is evidence of unskillful horsemanship.

4—Dashing, brilliant driving—that is, quick headway and a hard brake stop—is destructive to tires, just as a "crack the whip" start and sudden stop ruins horses' tendons and ankles.

5—Never twist a stationary tire on rough surfaces. This refers particularly to turning the front wheels, but the rule is applicable to the rear tire in starting and stopping.

6—Plug small cuts down to the fabric to prevent rotting and sand separation of the tread.

The Kissel Motor Car Company, Hartford, Wis., is in receipt of a letter from J. B. Carnes of Canton, O., in which he states that his wife thinks so much of their KisselKar 6-48 machine that she has been driving it every day this winter in preference to her electric. The Kissel company considers this one of the highest compliments that could be paid to a gasoline motor car.

MECHANICAL NOTES FOR OWNERS.

Outlining Components of Bosch DU4 and ZR4 Dual and Independent Magnetos and Hints for Adjusting Interrupter Mechanism---How to Test for Troubles.

BOSCH magnetos are standard equipment on a large number of 1914 cars, and while they require little or no attention other than an occasional oiling, a knowledge of their construction, operation and adjustment will be of distinct value to the owner in the event of trouble. After considerable service the break of the contact points may require attention or adjustment and to perform this work easily and successfully, one should be familiar with the components of the interrupter mechanism. Lack of space prevents giving specific instructions as to all types of Bosch instruments, but a description of the DU4 dual and ZR4 will enable one to deal with other models, as the principle involved is similar.

Both of these instruments are of the true high-tension type; that is, their armatures have a double winding, resulting in a high-tension current being produced in the magneto itself. When utilized in this form they are termed the independent type, so named because of the fact that a separate coil is not required to transform the primary current generated by the magneto.

The dual form, such as the DU4 and ZR4, which are also constructed for service with multi-cylinder motors, are also true high-tension magnetos, but employ two interrupters, which operate separately and distinctly from each other. One serves to interrupt the primary current generated by the magneto and the other breaks that supplied by the dry cells.

The term dual ignition is generally utilized to convey the impression that there are two sources of current available, and when employed in such manner is correct. In the simplifying of the automobile it has become general practise to use but one set of spark plugs, and although single ignition is growing in favor, many makers still

retain the dual ignition, but do not equip the cylinders with more than one set of plugs.

Formerly, and before the magneto was constructed to provide for the interruption of both its primary current and that of the battery, a commutator and coil were used with one set of plugs, and a magneto for the second set. This made for a network of wires, in that with a six-cylinder motor there was necessary 12 high-tension cables, six timer wires and those connecting the battery to coil, as well as the primary connections of the magneto.

Utilizing One Set of Plugs.

The development of the dual system eliminated the multitude of wires to a certain extent and has made possible the use of two separate

Dual Contact Breaker Used on Bosch DU4 and ZR4 Magnetos, Showing Components Utilized in Adjusting Break of Contact Points.

sources of current with only one set of plugs. This is made practical by employing the interrupter mechanism of the magneto in place of the commutator, and the distributor to distribute the high-tension current to the plugs. The Splitdorf instrument described in the last issue illustrates the point involved.

Independent Types.

The independent type, such as the Bosch ZR4, for example, is included under the head of single ignition, in that the instrument is utilized for starting as well as operating. It is the simplest form of ignition, in that there are but four wires leading from the distributor to the spark plugs, and one low-tension connection, that utilized

for grounding the primary current. This grounding diverts the primary current from the secondary winding and is accomplished when the switch lever is moved to the "Off" position. As previously pointed out, the single ignition is growing in favor because the general adoption of electric motor starters relieves the owner of cranking.

Components of Breaker Box.

If the novice will bear in mind the fact that the primary circuit of the magneto must be interrupted at a predetermined instant, and the break is timed practically in the same manner as in the commutator of the battery and coil system of ignition, the work of setting and timing magnetos will be greatly simplified. With the commutator, contact is made and broken between its roller and a metal block, closing and opening the primary circuit. With the magneto

lever comes in contact with either of the two segments in the housing. These segments depress the lever, breaking the contact between the points, which is normally maintained by the tension of a spring. While it would appear when watching the action of the parts that the points do not separate at all, they do very slightly—in the case of the Bosch instrument about .015625 inch. This is the proper distance to be maintained.

Adjusting the Points.

The Bosch points are adjusted by loosening the locking nut of the long screw with the wrench provided for this work, and rotating the long screw to the right to decrease the break, and to the left to provide a wider space. The Bosch wrench includes a steel gauge, a thin strip of metal, which is inserted between the points. It should be a slightly snug fit. This measuring should be performed when the fibre block is in contact with the segment, for in this position the points will be separated.

The components of the battery interrupter are shown beneath the magneto interrupter, and are contained in a separate housing. This construction is utilized with the Bosch DU4 and ZR4, also six-cylinder instruments of the same design. Were it not for the fact that a cam is fitted to the armature shaft for breaking the contact of the points, and the same set of spark plugs and switch utilized, the arrangement could be termed a true independent system.

When the switch lever is moved to the "Battery" side, the primary current of the magneto is ground-

The Wiring Plan of the Bosch DU4 System.

the interrupter mechanism performs the work, two platinum points making and breaking contact.

Operation of Interrupter.

The components of the Bosch dual contact breaker being shown, and, eliminating for the time being the parts employed for the battery circuit and studying those contained in the circular shaped housing, the operation will be easily understood. One of the best methods is to remove the breaker box cover and have some one crank the motor slowly while the working of the parts is noted.

It will be seen that the parts marked "long and short platinum screws" in the illustration, comprise a fixed member and a movable one. The long is fixed, but the short is moved away from it when the fibre block of the interrupter

ed. The battery current is led to the lower interrupter mechanism; is next transformed into a high-tension by a coil, and is conducted by a cable to the distributor of the magneto. Here the secondary current is distributed in the usual manner.

The battery interrupter of the ZR4 magneto is shown, but that employed with the DU4 dual instrument is similar, differing only in that the adjusting screw is located outside of the housing. The adjustment of the points is made in the same manner as with the independent type, but the distance or break of the points is slightly larger.

Wiring Plan.

The wiring plan of the DU4 dual magneto is shown in sketch, and connections are practically the same for the ZR6, differing in that six secondary cables are employed between the dis-

tributor and the spark plugs, and that two high-tension leads are employed between the switch and the magneto. The independent magneto requires but one switch wire in addition to the spark plugs leads, but in the dual system there are four connections between the switch and the magneto.

Two of these are high-tension, consisting of wire No. 3, by which the high-tension current from the switch is led to the switch contact, and wire No. 4, by which the high-tension current from either the magneto or the coil goes to the distributor. Wire No. 1 is a low-tension, and conducts the battery current from the primary winding of the coil to the battery interrupter. Low-tension wire No. 2 is the grounding wire by which the primary circuit of the magneto is grounded when the switch lever is moved to "Off" or to the "Battery" position. Wire No. 5 leads from the negative terminal of the battery to the coil, and the positive terminal of the battery is grounded by wire No. 7. A second ground wire is employed, the No. 6, it being connected to the coil terminal.

These terminals are plainly marked on the back of the coil and are accessible by removing the cover plate, which is retained by a knurled screw. By following the wiring plan a novice can remove and replace the wires without trouble and correctly.

The operation of starting with this form of coil does not require any explanation to its users, nor is there any attention required. If the battery is in good condition the wires properly attached and the contact points properly set, failure to operate on the battery side will require the services of an expert. The owner should not attempt to dissect the coil to see how the parts are assembled. It will not give trouble if properly used.

Detecting Faults.

If the motor operates properly on the magneto and misses on the battery side, it will usually be the fault of the battery. If the latter is in good condition, remove the battery breaker cover and note if the lever works properly and the points are clean and have the right break. The coil may be tested by disconnecting the No. 4 wire from the magneto and throwing the switch lever to the "Battery" side, operating the press button with the terminal of the wire held about .03125 inch from the metal of the motor. If the coil is not at fault, a spark will jump the gap. If this test fails, displace the No. 3 wire and repeat the experiment. In the event of serious trouble it is best to have the switch and coil ex-

amined at a Bosch service station, or inspected by an expert.

Testing Magneto.

Missing when operating on the magneto is generally due to a faulty plug or broken down insulation of the secondary cables. Too wide a gap may cause missing at low motor speeds and the space should be maintained in accordance with the instructions of the maker of the car.

Relative to the care of the distributor: There is little to be done other than to clean it with a soft, dry brush. Oil should not be utilized. The only place requiring lubrication is denoted by the word "Oil", and the owner should use judgment, employing a few drops every 1000 miles. Too much oil will invite serious trouble.

ANOTHER CASE IN COURT.

Judge Orders Cash Paid for Stock Returned to Man Who Made Investment.

As was pointed out recently in these columns, it is unfortunate that the great public interest in cyclecars appears to afford opportunity for business practises which have little place in an industry of the character and importance represented by the manufacture of automobiles. Another example is brought to light in the recent court action against Andrew De Schaum in Detroit, as a result of which Justice Richter ordered De Schaum to return \$500 to Joseph Koplitzki, who had invested it in so-called syndicate stock of the Automobile Cyclecar Company.

It was brought out that the company had not actually been organized, and the defendant insisted that he had not sold shares therein, but membership in the syndicate. On the witness stand, De Schaum testified that in his office he had material for six cars, but a personal investigation by Justice Richter failed to convince the court. It is stated that the transaction in question took place before the so-called "blue sky" law in Michigan went into effect in August.

Mitchell May, secretary of state in New York, estimates that there are in use throughout the world some 2,000,000 automobiles. He claims to have secured statistics from reliable sources which lead him to believe there are 1,127,940 cars in the United States, 425,838 in Great Britain, 273,511 in Europe and 92,500 in all other countries.

The Goodyear Tire & Rubber Company, Akron, O., maker of Goodyear tires and inner tubes, added 2500 men to its payroll Jan. 1.

IN THE COMMERCIAL VEHICLE FIELD.

Philadelphia Fire Department Needs Motor Apparatus--Features of Adams Truck Chassis--Interesting Trailer and Dumping Body Equipments.

AS A RESULT of a careful and detailed investigation, covering a period of 15 months, George D. Porter, director of public safety in Philadelphia, Penn., feels that he is compelled to report to the mayor and city councils that the fire department apparatus is in an antiquated condition, and that it is from five to 10 years behind that of many other cities. He maintains that \$2,870,000 is needed to modernize the department and bring it to an equal footing with other cities of the size of Philadelphia.

It is not the plan of the director, as set forth in his official report, to expend this sum at once. It is probable, however, that manufacturers of motor driven fire fighting equipment will have opportunity to bid on about \$600,000 worth of

There are 16 aerial trucks, of which one is of modern construction. Of the large number of combination hose wagons, nearly all are reported in bad condition, and only two are motorized. There are 14 fuel wagons, or tenders, all of which are horse drawn, and a majority are held to be beyond repair. Director Porter has recommended that these be replaced by motor trucks.

ADAMS TRUCK CHASSIS.

Constructional Features of a Line Produced with Three Capacity Ratings.

The Adams Bros. Company, Findlay, O., which has had long experience in the manufacturing field, and has been building Adams trucks for a number of years, is now producing these vehicles with load capacities of 2000, 3000 and 4000 pounds. The three chassis are practically identical in design and construction, except for the dimensions of the components. The accompanying illustration presents the one-ton model, and

Knox-Martin Tractor in Service with the Philadelphia Fire Department.

work in the near future. Mr. Porter has received the assurance of Chairman Connelly of the councils' finance committee that the appropriations requested to put the fire department on an up-to-date basis, in point of equipment and other necessary features, will be passed without any objections from the councilmen.

The recommendation of the director is that 34 of the old style fire engines be replaced immediately by motor driven pumping apparatus. He shows that the need for these is very acute, and estimates that the cost of this equipment will be about \$350,000. The total value of apparatus now in use is placed at \$246,933.50, of which the motor driven equipment is represented by \$66,189. There are 17 motor vehicles now in service,

a description of it will apply to the others, with the exceptions noted.

The motor is a Continental, of the water-cooled, four-cylinder, L head type. The cylinders are cast en bloc, with a bore of 3.75 inches and stroke of 5.25, giving an S. A. E. rating of 22.5 horsepower, although it is conservatively rated by the maker at 30. The two larger machines utilize the same motor, which has bore of 4.125 inches and stroke of 5.25, giving a rating of 27.25 under the S. A. E. formula. The maker's rating is 35. Lubrication is by plunger pump and splash, cooling is by centrifugal pump, ignition by an Eisemann magneto and the carburetor is of the automatic float feed type.

The clutch is a dry disc type, and this is

Plan View of One-Ton Chassis, Produced by Adams Bros. Company, Findlay, O.

mounted with the engine in a sub-frame. The transmission gearset, which affords three forward speeds and reverse, is assembled with the jackshaft and is supported at three points. Final drive is by side chains. Both axles are of the Timken manufacture, the front member being an I section and the rear rectangular.

The frame is a pressed steel channel section five inches wide, and is supplied with numerous cross members and sturdy gusset plates and braces. The forward end is necked in to permit full swing of the wheels in steering. The radiator is mounted in front of the dash, a type of construction which has been followed consistently by this concern from the first. The springs are semi-elliptic throughout. The service brake is contracting on the jackshaft, and the emergency expanding on the rear wheel hubs.

The one-ton machine has wheelbase of 121 or 136 inches and tread of 56. The front wheels are fitted with 3.5-inch, and the rear members with four-inch solid tires. The 1.5-ton wagon has the same wheelbase, and the front tires are 3.5-inch single, while the rear are dual of the same cross section. The two-ton vehicle has wheelbase of 140 inches and tread of 60. The tires are four inches in cross section, single in front and dual in the rear.

The driver is located at the left in each instance, and

the maximum body length back of the driver's seat with 121-inch wheelbase is 108 inches, with 136-inch wheelbase, 132, and 140 inches, 138. The chassis is sold with a seat having capacity for two persons, and the equipment includes oil dash and tail lamps, horn, oil can, tool kit, set of wrenches and jack. Painting can be furnished at the option of the purchaser.

PEERLESS TRUCK AND TRAILER.

General Electric Company Saves Original Cost in First Nine Months of Service.

By the use of a special Peerless truck, made by the Peerless Motor Car Company, Cleveland, O., and a trailer, the National Lamp division of the General Electric Company, has realized an economy equal to the original investment in nine months. The latter company has a glass factory in Niles, O., and the bulbs utilized for making incandescent lamps are produced there. It is necessary to deliver these bulbs at the lamp factories in Youngstown and Warren, and the plants in these cities can only be kept in operation by continuous delivery.

Formerly the bulbs were set by freight, and to

Peerless Truck and Trailer Utilized in Haulage of Electric Light Bulbs.

minimize breakage it was necessary to pack each bulb, wrapping it in tissue paper and placing it in a tray. The labor of packing was considerable, and despite the greatest care many were broken in transit. In addition, there was the freight charge to be taken into consideration. The bulbs are very light, but bulky, and the carload was based on bulk, not weight.

The company decided to experiment with highway haulage, and purchased a special Peerless chassis, with wheelbase of 204 inches. On this a van body was installed, this having inside dimensions of 17 feet eight inches length, seven feet width and eight feet four inches height. This body has outside sliding doors.

The weight of a load for this body, which will

be very close to that for rail shipments in carloads, but the saving is represented in the elimination of the labor incidental to packing and unpacking, and in the lessened liability of breakage. The roads between Niles and Youngstown are dirt, worn macadam and brick. The average daily mileage is 35, and the load will range from 3000 to 4000 pounds.

BAKER DUMPING TRUCK.

A Body Installation Design for Handling Fuel, Etc., by Electric Machine.

An accompanying illustration presents the quick discharging body designed for use with the standard four-ton Baker electric chassis, built by the Baker Motor Vehicle Company, Cleveland, O. The body can be installed at the option of the purchaser, and is constructed with a frame of angle iron, and sides and ends of steel plates, these members being riveted. The floor is of steel channels covered by steel plate. The tail lever is opened and closed by a lever mounted at the side of the driver's seat.

New Steel Dumping Body Designed for Use with Four-Ton Baker Electric.

hold 1030 cubic feet, was less than a ton, and to utilize the additional power of the motor a trailer was built, this having a frame of channel angle iron mounted on springs and truck front and rear axles, the wheels being of standard size and shod with solid tires. The trailer is controlled by a drawbar or pole, that has a short arm or lever that is linked to the chassis frame, with a longer lower arm pivoted on the front axle connected with the centre of the tiebar that extends across from the tail levers on the front wheel pivots. On this trailer was installed a body of the same size as that on the truck chassis. The combined capacity equals that of the average box freight car.

The actual cost of haulage has been found to

be by hand or by motor. The body can be elevated to an angle of 45 degrees, and is hoisted by means of two arms secured to the sides below the floor. These arms are actuated by a large steel cross shaft that is installed transverse of the chassis frame, and revolves in one direction only. Two-thirds of one revolution is required to elevate the body, and the other third will lower it.

It will be noted by study of the illustration, that the body is hoisted by a shaft extending longitudinally of the chassis. This carries a worm that meshes with a worm wheel, which in turn drives a train of reduction gears that actuate the cross shaft. This shaft is amply lubricated, the bearings being in oil tight housings,

and it may be driven by an auxiliary motor, supplied with power from the battery, or it may be turned by hand.

Sizes of standard bodies for handling differing materials are: Coke, 11 and 14 feet length, four and six feet width, and three feet height; coal, 10 and 14 feet length, four and 4.5 feet width, 1.5 and two feet height; sand, 10 and 14 feet length, four feet width, one and 1.5 feet height. The last dimension includes three-inch flareboards.

CONSIDERING TRUCK COSTS.

A Statement of Present Conditions Presented by an Engineering Expert.

The communication presented below is submitted to the consideration of business men who may be interested in the subject of motor truck haulage. The writer is Walter M. Curtis, manager of the engineering department of the New England Audit Company, Springfield, Mass.:

Before the advent of the motor vehicle for commercial use, very few business concerns took the trouble to find just what their trucking charges amounted to. Inasmuch as the horse was the only means available for the purpose and had to be fed anyway, whether working or not, there was comparatively little inducement to separate the teaming cost from other expenses. Occasionally a concern might wish to know whether it would be cheaper for it to maintain its own teams or to put out its trucking on contract, but this was practically the only incentive for watching the trucking charges closely.

The advent of the motor vehicle and the necessity of intelligently considering its adoption to their own particular line, awoke business men to the importance of knowing what their trucking was costing them. It called for more than this, for other considerations were involved, such as the advertising value of a motor vehicle, effect on customers, advantage over competitors, stimulation of trade, etc. Disregarding these latter features, however, the great problem confronting business concerns has been to secure a reliable basis upon which to compare the two systems from a cost standpoint.

Although it may not be possible to give actual figures on the saving a motor system can effect in any particular instance without a special study of the peculiar conditions involved, I have found it entirely practical to make an analysis of the proper charges to be taken into account in both horse and motor vehicle trucking methods in various lines of industry. These charges fall naturally into two classes—fixed charges and operating charges. In the former are placed interest, insurance of all kinds, drivers' wages and garage charges. In the latter, depreciation, gasoline, oil and grease, tires and general maintenance.

By a careful study of much of the reliable data obtainable on these subjects and an analysis of the results in accordance with the above general classifications, I have found the following to be very clearly apparent: First, that there is a decided advantage in the use of motor vehicles of large capacity whenever the nature of the load is such as to make a large tonnage possible; second, that there is a corresponding reduction in the cost a ton-mile with an increase in the daily mileage; third, that it is of the greatest importance to eliminate as much idle time as possible in the use of motor vehicles; fourth, that rubber tire expense is a large direct operating charge in the case of the regulation motor truck; fifth, that a comparison of the charges against the tractor type of motor vehicle with those against the large regulation motor truck shows a distinct economic advantage for the tractor for many purposes, due

mainly to the following reasons: Larger capacity at a less investment cost, less strain and consequently less damage and maintenance to vital parts for the same tonnage, also less tire expense due to use of steel tires under the greater part of the paying load.

With these conclusions in mind, it should not be difficult for a business man to judge with some degree of accuracy, whether or not a motor truck or a tractor would be of value in solving his own particular hauling problem. He could then obtain outside expert advice in arranging the details of his case if he felt it necessary. In many cases a rearrangement of the shipping facilities would make it possible to use a motor vehicle to great advantage, when under present conditions it could not be worked to a proper capacity. Even where no great financial saving can be effected, as in some cases of short haul work, the motor vehicle is a good asset from an advertising standpoint—it invariably tends to increase trade and pleases customers by more prompt and efficient service.

Some time ago I had occasion to render a report upon trucking costs to a client, a prominent eastern manufacturer. This report later appeared in printed form and an idea of the widespread interest in this subject at the present time can be gained from the frequent requests received, according to a recent communication, for copies of this report, indicating that business men are rapidly becoming educated to the importance of giving careful attention to their trucking problems.

WHY KEEP TO THE RIGHT?

Some Historical Reasons for the American Custom in This Respect.

With the more general adoption of left hand drive in this country, motor car manufacturers are beginning to give special attention to the reasons which first impelled Americans to keep to the right, instead of the left, as in European countries. The matter was brought up in the factory of the Moon Motor Car Company, St. Louis, Mo., recently, because of the number of orders coming from abroad, in which it was specified that the car should be fitted with right hand drive.

Stewart McDonald, vice president of the Moon company, has been delving into the history of this matter, and explains the situation as follows: In Europe, in the days of the spear and sword, a horseman kept to the left in meeting anyone, in order that he might have his adversary, if such he proved to be, on the free or right side. In this country, horseback was the first general mode of travel, and in meeting an adversary the horseman kept to the right in order to have the enemy on the protected side, the horse's body and neck forming a shield and his own body protecting his gun arm.

The L. W. Rinear Company, Cleveland, O., discontinued its advertising office in that city Feb. 1, and of the men connected with the company, Mr. Pierce and Mr. Rinear will continue their work through the Miller Agency Company of Toledo, O.

ACETYLENE AS AN EMERGENCY FUEL.

OPERATING the motor on acetylene when the fuel has become exhausted, and starting the engine when cold by priming the intake manifold have been accomplished by motorists and the methods utilized have been outlined in these columns. The Prest-O-Lite Company, Inc., Indianapolis, Ind., maker of Prest-O-Lite tanks, has received many reports from owners who have made emergency use of acetylene as a fuel, and in some instances considerable mileage was obtained from a 40-foot capacity tank. One of the four-cylinder cars from the Prest-O-Lite garage was employed on the Speedway track, and it ran 11 miles at a rate of 22 miles an hour with one 40-foot supply of acetylene.

Fig. 1—Prest-O-Primer Valve for Emergency Fuel.

About a year ago the Prest-O-Lite Company brought out the Prest-O-Primer for aiding motor starters. The outfit included an automatic reducing valve for the tank, a line to the dash, and a push valve convenient to the driver. Operating the valve admitted acetylene to another pipe connected with the intake manifold. Releasing the valve shut off the supply. To prevent leakage an extra needle valve was incorporated in the dash control. The operation of the system was simple. The low pressure acetylene was drawn in in the conventional manner, and the mixture was fed until the engine became sufficiently warm to operate under the regular fuel.

The acetylene mixture being readily combustible, starting was assured in low temperatures. The Prest-O-Lite Company states that many motorists whose cars were not equipped with motor starters have attempted

Fig. 2—Prest-O-Primer Used with Hand Cranking.

alterations to the primer, changing the construction so that the gas would flow while they went to the front of the machine to crank. This is not recommended by the company, as careless operators are apt to forget to shut off the supply, even after completing the trip. The combustible nature of acetylene is such that accidents might ensue through neglect.

The Prest-O-Lite Company has brought out a device for the benefit of those who crank their motors and who use the primer. The arrangement is shown at Fig. 2 and consists of a lever attachment to the dash valve. A wire leads from the lever to the front of the car, enabling the driver to operate the primer while he spins the motor much in the same manner as the butterfly valve of the carburetor is held closed when a rich mixture is desired. The dash valve is held open by the wire until the motor has become warm. Releasing the wire automatically closes

Fig. 3—Showing the Installation of the Prest-O-Primer, Permitting of the Use of Acetylene for Starting and Operating.

the valve. In connection with the device the company states that better results will be obtained by closing the butterfly valve of the carburetor, and suggests that the motor be run a few seconds on acetylene, then the supply shut off and note if the engine operates on gasoline. If not, the dash valve is opened until the desired results are obtained.

It is important to retard the spark, especially if the motor is to be started on the magneto, as the acetylene mixture ignites much more quickly than gasoline, and the company states that this holds true in cold weather.

Relative to the use of acetylene as an emergency fuel: Fig. 1 shows the use of the dash Prest-O-Primer. It is easily operated, the driver pushing in the valve plunger by the foot, which permits acetylene to flow to the intake manifold. The motor will continue to operate on acetylene as long as the valve is pushed in and until the

supply is exhausted. The spark should be retarded, and the company states that it should be remembered that, as the gas pressure is constant, the richness of the mixture must be controlled by the opening of the throttle, thus admitting more air through the carburetor. It is also stated that it is a simple matter to ascertain the correct throttle positions under all conditions of operation.

The use of acetylene for cranking or as an emergency fuel does not interfere with the lighting, as a two-way union is attached to the tank, so that one branch will run to the lights and the other to the priming device. When so used the gas is turned on at the tank, a separate valve being provided for the lights, and the gas for the priming device is controlled by the dash members.

TO LOCATE IN NEW HAVEN.

Westinghouse Air Spring Company Said to Have Secured Plant in That City.

The Westinghouse Air Spring Company, which has had temporary offices in New York City, is said to have purchased the shop of the U. S. R. F. G. & P. Company in New Haven, Conn., where it will locate its factory for the production of Westinghouse air springs for automobiles. It is understood that formal occupation of the plant will be made within the near future.

For some little time past, the air springs, which are in the nature of a shock absorbing device, have been made in a small shop in Ansonia, Conn. The workmen and machinery employed in that city will be removed to New Haven, under the plan as made public.

FLYING MERKEL NEWS.

Several Changes in Personnel of Men Who Help Sell Well Known Motorcycle.

On account of the rapidly growing business of the Miami Cycle & Manufacturing Company, Middletown, O., maker of Flying Merkel motorcycles and a number of well known brands of high grade bicycles, it has been found necessary to reapportion the districts in the United States. This has resulted in a number of changes in the personnel of the sales organization of this concern.

E. W. Adams, who has charge of sales on the Pacific Coast, will retain as his territory, Wash-

ington, Idaho, Arizona, California, Nevada, New Mexico, Oregon, Utah, Alaska, Hawaii and British Columbia. O. K. Newby, who has been in the East, and J. E. Steuer, who has been in New England, will assist him.

F. P. Lee, in charge of the central western district, will have as his territory, Wyoming, Nebraska, Colorado, Kansas, South Dakota, Iowa, Missouri and a part of Illinois. Hans Johnson of Dallas, Tex., will handle the Flying Merkel in Oklahoma, Louisiana and Texas, and the Elyes Austell Company of Atlanta, Ga., has arranged for the distribution in the South Atlantic states.

William McKinley Sheets, whose picture is presented herewith and whose record has been so good in the East during the past year, has been promoted to have charge of the sales in Indiana, Kentucky, Arkansas and portions of Tennessee, Illinois and Wisconsin. John Newberry will direct the sales in Michigan, Ohio and West Virginia; W. K. Thomas in Pennsylvania, Mary-

Two Flying Merkel Salesmen: At Right, William McKinley Sheets; at Left, Ralph K. Smith.

land, Virginia and Delaware, while C. A. Vandoren will retain control of the New England territory, with the addition of New Brunswick and Nova Scotia.

A decidedly important acquisition to the Flying Merkel force is that of Ralph K. Smith, for many years with the Pope Manufacturing Company. He will hereafter be known as the eastern district manager for the Miami interests. He was born in Maine, but soon removed to Boston. He spent several years on the road, and went with the Pope company in 1905. With the Miami concern he will have as his territory, New York, Pennsylvania (east of Harrisburg), New Jersey, Ontario and Quebec.

C. W. Siegmund, general manager of the Porto Rico Motorcycle Supply Company, San Juan, Porto Rico, has secured the exclusive distribution rights on that island.

IMPROVED ROADS AND MOTORING LAWS.

American Automobile Association Succeeds in Placing New Jersey Test Case on Docket of United States Supreme Court---Warns Law in Ohio.

MOTORISTS generally will be interested in the announcement that Charles Thaddeus Terry, general counsel of the American Automobile Association, has had placed on the docket of the United States Supreme Court, the so-called New Jersey test case, and it is expected that it will be argued before the year is ended. The case is being handled by former United States Attorney-General J. W. Griggs of Paterson, N. J., who represented the Associated Automobile Clubs of New Jersey during its progress through the state courts.

Several years ago the White Company started a truck from its New York City branch, carrying a load of parts for its branch in Philadelphia, and attempted to cross New Jersey without first procuring a Jersey license. The test case resulted. The Associated Automobile Clubs of New Jersey contended that the registration fee in question constituted a tax which interfered with interstate commerce. The matter eventually was taken to the New Jersey supreme court, which held, in effect, that the fee, which at that time was comparatively low, was not sufficient to constitute a tax, being more in the nature of a fee to provide the necessary funds for the administration of the law, which came within the police powers of the commonwealth.

There the matter was permitted to rest for some time, or until last year, when the legislative board of the American Automobile Association decided to take the case into the federal courts. It will be understood that the question involved is a specific one, and does not include the broader question of double taxation, which was brought in Mississippi and some other states.

THE LAST TOLL ROAD.

Vermont Legislature Seeks to Abolish the Only One in New England.

Steps have been taken by the Vermont legislature to acquire the stock in the only toll road existing in New England, that covering the six miles between Peru and Winhall, Vt. The stretch of road is included on the Ideal Tour from New York to the Berkshires, etc., and has been a source of considerable annoyance to motorists

for some years, not alone because of the necessity for paying toll, but because of the antiquated construction of the road itself, with its numerous "thank-ye-marms."

The road was built in 1815 by Gen. Peter Dudley of Peru, Vt., at a cost of \$5000, and the builder maintained it for 20 years. Later the property passed into the hands of a corporation and for some years a considerable proportion of the stock was held by residents of Peru and Winhall. The shares paid no dividends, and it is stated that the present owner, John J. Flynn, a wealthy contractor of Burlington, Vt., acquired the shares without much difficulty. His first price to the state was \$3000, but it is understood that this has now been advanced to \$15,000.

ON LINCOLN HIGHWAY.

Old Ferry Road in New Jersey Is Oldest Portion of Transcontinental Route.

It transpires that the Essex-Hudson section of the Lincoln highway, in New Jersey, undoubtedly is the oldest portion of the transcontinental route in which the Lincoln Highway Association is interested. It also is believed to have been the most expensive to construct.

This historic highway was established by the Colonial legislature in New Jersey, which called upon "all good people" to "assist in keeping it fit for travel." A public notice in the New York Gazette, June 27, 1865, declared the highway "would run from New-Ark to the public road near the Town of Bergen, leading to the Paulus-Hook and established Ferries over the two small Rivers, Passick and Hankingsack, which makes the Distance from Paulus-Hook to New-Ark eight miles and will be a level and good Road when the Cause-ways are made."

It was first known as the "Ferry Road" because the Passaic and Hackensack were crossed on ferries. After the bridges were built extra heavy planking was laid crosswise on the road, and the name, by which the highway has been known for upward of a century, was the "Plank Road." The present road cost \$1,316,000, of which \$500,000 represents the cost of bridges. The highway is now 100 feet in width, with 10-foot sidewalks on either side, and two 28-foot road-

ways. Trolley tracks are raised 12 inches in the centre.

NO COMPROMISE IN OHIO.

Legislators Seeking to Secure an Agreement with State Association.

The taxation committee of the Ohio house of representatives, which, with the senate, has been called in special session to consider the matter of again passing the Warnes law with changes which will bring it within the constitutional limitations, has invited representatives of the Ohio State Automobile Association to a conference in order to learn if it is possible to effect a compromise. Two propositions are being considered by the legislators, one of which provides a flat rate of \$6 a car, and the other, a sliding scale from \$5 to \$10, based on the horsepower rating. The association objects to the latter.

It is understood that the motorists will decline to compromise with the legislature, reserving the right to attack any law in the courts. As a result of declaring the Warnes law unconstitutional the state registrar of automobiles has laid off all of his force except one deputy. All remittances received for 1914 tags, before the court decision was handed down, have been returned, and at present there is no registration law in Ohio.

TO WELCOME TOURISTS.

Massachusetts Expected to Repeal 10 Days Clause in Existing Law.

The state highway commission in Massachusetts has suggested to the legislature now in session that it would be quite proper to repeal that section of the motoring law which states that a non-resident may not stay within the borders of the commonwealth more than 10 days without being required to register his car. As a matter of fact, this has been somewhat in the nature of a dead letter in many instances, while in others it has been rigorously enforced. There seems to be a fair probability that the action suggested will be taken.

The Automobile Legal Association also has filed a petition to amend the registration law, so that the fee may be reduced 25 per cent. on cars registered between April 1 and June 30, 50 per cent., between July 1 and Sept. 30, and 75 per cent. between Oct. 1 and Dec. 31. The present reduction is 50 per cent. after Oct. 1. The

association maintains that, inasmuch as the purpose of the law seems to be to remunerate the state for alleged damage done to the highways, it should follow that one who uses the highways for nine months does not do as much damage as one who uses them the entire year.

CHOOSES PREMIER CAR.

Vice President Westgard of National Highway Association on Another Trip.

A. L. Westgard, vice president of the National Highway Association, which has its "workshop" at South Yarmouth, Mass., has returned from an 18,000-mile trip in the interests of that association, and is about to leave on another journey of 20,000 to 25,000 miles. Every character of road will be traversed; all the great mountain ranges will be crossed, and in many sections roads will be attempted over which no automobile has yet been driven.

Mr. Westgard has crossed the continent six times, besides making a large number of trips from the Lakes to the Gulf. On most of these trips he has utilized a Premier car, made by the Premier Motor Manufacturing Company, Indianapolis, Ind., and he has made selection of one of these machines for his forthcoming journey. Concerning this make of machine he has the following to say:

I use a car that will run continuously under all sorts of conditions of apologies for roads and weather, without any thought of trouble. Frequently, I flounder through seas of mud, hundreds of miles from nowhere, and, the next day, climb hills that would break the heart of the ordinary automobile. Good roads? That's what we hope to get. If we had them perhaps something besides the Premier might serve me, but while I still am rambling about the country blazing the trail, I will pin my faith to Premier.

The Aero Club of America announces that it will co-operate with the management of the Panama-Pacific exposition in arranging plans for an aeroplane race around the world, to start from the exposition grounds in San Francisco in May, 1915, and to be completed within 90 days. The first prize will be \$100,000.

The fourth annual automobile show of the Tiffin Daily Advertiser will be held in the Junior O. U. A. M. auditorium, Tiffin, O., March 4-7, under the management of E. T. Rogers. Every effort will be made to make this show "prettier than ever", and the local dealers will practically all be represented.

MACHINERY, TOOLS, EQUIPMENT AND SUPPLIES.

THE Cox Brass Manufacturing Company, Albany, N. Y., has brought out the Cox combination welding and decarbonizer outfit, which, as the name implies, provides an equipment

Cox Welding Equipment in Service.

for removing carbon by the oxygen process and for welding broken parts. It has several advantages, the most prominent of which is, perhaps, the saving of time. Ordinarily the work is sent outside, which generally results in delays, and, in addition, the profit accruing to the garage man is very small, this usually being a percentage. And it sometimes happens that a small repair is desired in a hurry by the customer and that the welding company is not able to handle the work.

With the Cox outfit the welding work may be performed quickly by the repairman, and the company states that the operation of the equipment can be learned in a very short time by the average mechanic. One of the qualities emphasized by the apparatus is that it will do the work thoroughly, welding broken parts made of brass, steel, iron, bronze, copper and aluminum. With the equipment it is obvious that many repairs formerly requiring considerable time with old methods can be made quickly.

The process of welding is well known. The principle of the method is the use of a small concentrated flame of a temperature approximating 3600 degrees Fahrenheit, applied directly to the metals to be welded.

The Cox dual equipment comprises a highly polished oak case, nickel trimmed, with cover and handle as shown in the accompanying illustration. The case contains a welding torch with six interchangeable tips, sufficient to perform welding on all kinds of work; one oxygen reducing and regulating valve, with gauge and shut-off; one acetylene reducing valve, with gauge and shut-off, fitted with special coupling for attaching to Prest-O-Lite gas tank; 12 feet of acetylene hose, 12 feet of oxygen hose and a complete assortment of welding rods for welding copper, brass, iron, bronze, steel and aluminum. The wrenches, goggles, etc., are packed in a special, convenient case.

In addition there is included a decarbonizing torch and swab for removing carbon from motor cylinders by the oxygen process. The last named provides the dual equipment to which reference is made above.

The Cox Brass Manufacturing Company calls especial attention to the low cost of the apparatus, which is marketed as a unit or separately. A special gauge for showing the supply of oxygen on hand is listed at a slight extra cost. The company supplies complete instructions for the use of both systems, and maintains a free service department for the benefit of its customers. One of the features of the department is the expert information supplied for repairs out of the ordinary.

The company calls especial attention to the regulator or reducing valves, stating that they are so constructed as to automatically reduce the pressure of the oxygen from that of the tank of 1800 pounds, and that of the acetylene tank from a pressure of 200 pounds, to a low, workable pressure of from zero to 25 pounds. The pressure is regulated to an even consistency and does not vary from a set amount. Complete details and price lists will be forwarded upon application to the company.

COCHRAN PIPE WRENCH.

The Cochran Pipe Wrench Manufacturing Company, 78th street and Woodlawn avenue, Chicago, is marketing the Cochran pipe wrench shown in an accompanying illustration. It is warranted to give 50 per cent. more service than

Case Containing Tips, Valves, Etc., Utilized with Cox Combination Welding and Decarbonizing Outfit.

conventional designs, and the guarantee is very liberal. One of the qualities of the tool emphasized is that the compression strain is exerted on

Cochran Pipe Wrench Having a Solid Frame and Movable Hook Jaw.

that part of the member which is the strongest.

The frame and handle are one solid piece, and a rocker replaces the usual pin, eliminating opportunity of shearing stresses. The jaw is of the hook type and is with the inserted jaw, drop forged from the best grade of tool steel. The rocker and adjusting nut are also constructed of high grade material.

The maker claims a perfect grip and release by its construction, and states that the tool cannot be injured by a side pull, owing to its solid frame construction. It is guaranteed not to crush or lock on pipe. The Cochran wrench is made in six, eight, 10, 14, 18, 24 and 36-inch sizes, taking from .125-inch wire to 1.5-inch pipe for the smallest size, and upwards for the larger wrenches. All parts are standard and interchangeable.

COMMON SENSE BORING TOOL.

W. W. Blakely, 100 Leicester Court, Detroit, is manufacturing the Common Sense boring tool, made in two parts, and designed for service on milling machines, lathes, etc. The shank and barrel are integral, and the dial and holder are combined. The tang of the tool does all of the driving and calibration is by the vernier system reading in thousandths. Throwing the two eccentrics opposite each other centres the bar, and changing the inner eccentrics' position enlarges the cut, giving a total expansion of .5 inch or more. It is made with .625, .75 and .875-inch boring bars. A toolmaker's size is also made. Prices and particulars will be forwarded by the maker on request.

UNIVERSAL HACKSAW MACHINE.

Power hacksaws are time savers in the repair shop and service station, as not only is consid-

erable time wasted in cutting metal by the hand tool, but with large pieces it is not always easy to make an accurate cut. The West Haven Manufacturing Company, West Haven, Conn., produces a line of hacksaw frames and blades, and is marketing the Universal hacksaw machine shown in an accompanying illustration. It has a capacity of six-inch solids, and one of the qualities of the equipment is the quick return of the stroke, this being 3:1. The blade also lifts entirely from the work on the return stroke.

The machine is designed especially for economy and speed. There are two fixed strokes, a five and a seven-inch, and only one adjustment is required; that is, for work above five inches in diameter or square. The maker states that the adjustment may be made in the short time of 15 seconds. Another feature of the machine is that the automatic lift is adjustable for wear. It is stated that the automatic stop is absolute, and that the pulley can be lubricated without throwing off the belt. The company calls special attention to the shafts of the machine, stating that these are silent, and being on the bed of the machine make for maximum service. All parts are interchangeable.

The size of the pulley employed is six by 1.75 inches and the speed is 240 revolutions a minute. The length of the saw blades is 12 and 14 inches. The floor space required is 52 by 16 inches; height of work vise, 28 inches, and height over all, 42 inches. The net weight is 240 pounds; gross, 300. All castings are numbered, making for convenience when ordering spare parts. The company issues a catalogue of its products, which will be mailed free on request. The West Haven Manufacturing Company makes a specialty of hacksaws, producing them to meet all requirements, such as cutting solid metals, tubing, etc.

Universal Power Hacksaw Machine Having Rapid Return of Stroke and Being Capable of Cutting Solids up to Six Inches in Diameter.

NEW DEPARTURE'S OFFICE BUILDING.

SOMETHING like 25 years ago, the New Departure Manufacturing Company, Bristol, Conn., maker of New Departure ball bearings, etc., started business in a small room containing less than 60 square feet. Today, it is occupying nearly that many square acres, with several millions of dollars invested in machinery, operated by 2000 skilled mechanics, busy day and night a greater part of the time. It has one of the most thoroughly equipped manufacturing plants in America. One entire building is devoted exclusively to the scientific study and analysis of steel and manufacturing processes, this structure housing chemical, metallurgical and physical testing laboratories, outfitted with the most modern apparatus.

The remarkable growth of this concern dur-

New Administration Building of the New Departure Manufacturing Company, Bristol, Conn.

ing the past few years has frequently made it necessary to provide large additions to its manufacturing facilities. A little more than a year ago the demand for New Departure ball bearings had increased so rapidly that it was impossible to await the erection of a new building, and the extensive plant of the Whitlock Coil Pipe Company, in Hartford, comprising 145,000 square feet of floor space, was purchased outright. This proved to be sufficient only for the time being, and it was decided to provide a new administration building, which has been in course of erection during the past twelve months, and is soon to be occupied by the company.

An accompanying illustration presents an exterior view of the structure, which is 62 feet wide, 220 long and six stories high, including the basement. The outer walls are of light gray tapestry brick, in three shades, relieved by broad ribbons of blue and green colored tiles in panel effect at

the second and fifth stories. The front entrance is approached by a broad flight of granite steps, and over it is a large copper marquise in verde antique. On either side of the entrance are large hand carved limestone panels.

The main vestibule has a quoin ceiling decorated in Roman gold. The side walls are panelled in marble. Verde antique is used with centres of Bresch opal. The floor also is of marble and tile, worked in geometrical design with the monogram of the company in green and white as the centre piece. The main lobby, just beyond, is 16 feet square, and has a floor of Italian marble with a border in the predominating verde antique. The wainscot is eight feet high and is worked in Bresch opal and scagliola, with ornamental capitals. The wall surfaces are ornamented with pilasters of Royal Irish scagliola. The ceiling is in simple design of pleasing colors, toning up the marble work. A dome in the centre permits the placing of the electric lamps in such manner as greatly to diffuse the light. At the corners are four smaller domes, with lamps similarly positioned.

The offices are located on the fifth floor, an electric elevator running thereto. At the front and south side are located the private offices of the officials and heads of departments. These are finished with panels of mahogany carried up to the window sills. The partitions in the general office are of plate glass above the wainscot.

The floor is tile and the ceilings have a simple Greek cornice worked in ornamental plaster in delicate shades of cream and apple green, which soften and intensify the light.

At the west side is a double fire and burglar proof vault of two stories. All equipment in this vault is of steel. The entrance is guarded by modern fire and burglar proof steel doors. Another feature of the main office is the large leaded glass dome ceiling light, 112 feet long and 16 feet wide, supported on pilaster columns of the Doric order. The colors in the dome are opalescent greens and ambers, which catch and diffuse the sun's rays without causing shadows.

On this floor, in addition to the general and private offices, is a large foreman's conference room with a small kitchen attached, equipped for serving lunches, etc. All office furnishings are of mahogany and the workers in each department are immediately opposite the head of that depart-

ment. The remainder of the building will be occupied principally by the inspection and assembling of the company's product. The first floor will be given over entirely to shipping and receiving.

Beginning Jan. 1, changes were effected in the organization, which are expected still further to develop the plant to its many possibilities. Albert F. Rockwell, who was one of the founders of the company and whose genius has developed the patents covering the company's product, has been relieved of certain managerial detail, but continues his duties as president.

Dewitt Page, who has been identified with the concern almost from its inception, and in later years as secretary, sales manager, purchasing agent and advertising manager, has been appointed general manager. Mr. Page is well known to the trade and brings to this position unusual ability, and a knowledge of the company's affairs in production and promotion that specially qualifies him for the duties.

Charles T. Treadway, who for some years has been treasurer of the company, continues in that capacity, and also becomes chairman of the board of directors, a position which makes him an important factor in the future development of one of the most successful New England enterprises.

SECURES LARGE ORDER.

Driggs-Seabury Ordnance Company to Build Them for Twombly Concern.

According to a special dispatch from Pittsburgh, Penn., the Driggs-Seabury Ordnance Corporation of Sharon, Penn., has been awarded a contract for the manufacture of 3000 automobiles for the Twombly Automobile Company of New York City.

It may be added in this connection that the Twombly Car Corporation, which has offices in New York City and produces the Twombly cyclecar (or light car, whichever it may be under the terms of the new definition), has a plant at Avondale, N. J., about 10 miles outside the Metropolis, where it is stated that the company has ample facilities for manufacturing these machines in large quantities.

Charles E. Wade, of the Chas. E. Wade Sales Company, Detroit, has been appointed sole selling agent for Barthel & Daly, New York City, importer of Schafer ball bearings, in the Middle West. He was with Rhineland Machine Works.

FORD'S CYCLECAR "JOKE".

Also Some Further Information Concerning the Ford Electric Car.

It has been no secret that Henry Ford of the Ford Motor Company, Detroit, has been keeping close watch of the cyclecar movement, and to some it has been made known that experiments had been carried on sufficiently to permit of certain manufacturing plans should occasion seem to warrant such action. As long ago as last November, it was stated by a man who had just returned from the Ford factory that a car of the cyclecar type had been produced by this concern, although there was no disposition to suggest at that time that Ford was preparing to enter the cyclecar field.

During the recent Detroit automobile show, which was held in the new Ford assembly building, a miniature Ford car, fitted with a four-cylinder motor, with bore and stroke of approximately three and four inches, respectively, was wheeled across a portion of the main floor under circumstances evidently intended to create the impression of concealment, although, in reality, everybody in the hall could readily observe what was going on. In this connection, it may be added that the Ford Motor Company has issued an absolute denial that it intends to build a cyclecar.

Apropos of the recent rumor that Henry Ford and Thomas A. Edison were working on a new electric car of light weight and low price, it is stated in Detroit, that Edsel Ford, vice president of the Ford Motor Company and son of Henry Ford, is to head the new company which will be organized for the production of this machine. Additional information suggests that the car will be made in Detroit, some time during the present year, and that it will sell for about \$600.

The Anderson Electric Car Company, Detroit, maker of the Detroit electric line of pleasure cars and trucks, reports that it has been working overtime for the past two months and that the orders for December were 20 per cent. in advance of the same month in 1912.

The Metropol Motors Corporation, New York City, which recently brought out a new four-cylinder car of large horsepower, is said to be interested in securing a factory site, and is addressing letters for this purpose to several boards of trade and similar organizations.

NEWS OF THE MANUFACTURER AND DEALER.

The following concerns have been incorporated recently to manufacture or deal in motor vehicles, accessories, etc.:

Bay City Auto & Sales Company, Bay City, Tex.; \$7500.
Kerosene Karburettor Kompany, Aberdeen, S. D.; \$500,000; W. B. McLaughlin, J. S. Tilney, George J. Hinds, Edward M. Skinner, H. G. Fuller.
Knuckey-Mysing Auto Company, New Orleans, La.; \$10,000; W. A. Knuckey, W. F. Mysing and others.
Motor Gasoline Company, Muskogee, Okla.; \$25,000; J. M. Givens, E. C. D. D'Yarmett, W. E. D'Yarmett.
Fort Wayne Supply Company, Fort Wayne, Ind.; \$50,000; Jeremiah M. Cramer, John A. Brewer, Harry H. Criswell.
Wentworth, Fosdick Company, Boston, Mass.; Frank Wentworth, Harry Fosdick, Edwin J. Carruthers.
Utah-Idaho Auto Company, Logan, Utah; \$25,000; Morgan Knapp, J. P. Griffin, Wilford O. Johnson, John Everton, W. H. Stewart.
Steel King Motor Car Company, Lansing, Mich.; \$100,000; E. S. George, S. T. Craple.
Somerset County Automobile Association, Somerville, N. J.; F. G. Thomas, Dr. George Voorhees, Dr. Ely, Dr. Naylor, John Case.
Morgan Auto Company, Sioux City, Ia.; \$50,000.
Durand Auto Company, Durand, Mich.; E. Henry, A. E. Van Slyke.
Cycle Manufacturing Company, Chicago, Ill.; \$15,000; George A. Chilton, D. C. Thorsen, Phillip Lawrence.
Bergman Bros., New York City; \$2000; H. Weinstein, M. Bergman, T. Bergman.
Columbian Auto & Motor Car Company, Port Richmond, N. Y.; \$5000; J. A. Wisely, F. F. Leman, E. T. Shortt.
McGraw Tire & Rubber Company, New York City; \$1000; R. F. Hobron, W. L. Levy, M. Davidson.
Ajax Auto Service, New York City; \$5000; A. G. McKeever, J. J. Bradley, J. P. Shinnick.
Trenton Motor Car Company, St. Louis, Mo.; \$10,000; J. L. Nugent, A. F. Becker and others.
United Auto Supply Company, Waco, Tex.; \$5000; R. S. Keyser, S. Zeve, S. W. Wexler.
Henderson Gasoline Company, Nowata, Okla.; \$200,000; W. O. Strother, J. Wood Glass, F. P. Peterson.
Automobile Club of San Antonio, San Antonio, Tex.; \$8000; W. A. Herring, Emil Frank, H. G. Staacke, Dr. Frederick Fielding, John B. Carrington.
Bond Auto Company, St. Louis, Mo.; \$10,000; H. M. Bond, C. Kist, C. Bond.
Automobile Funding Company of Seattle, Seattle, Wash.; \$500,000; F. W. Clay, C. A. Bradley.
Seattle Motor Speedway Corporation, Seattle, Wash.; \$200,000; J. C. Hayward, Harry W. Doherty, A. B. Simmernacher, Howard S. Amon, R. G. Dennev.
Rex Oil & Refining Company, Oklahoma City, Okla.; \$50,000; L. M. Pierucci, M. Luty, N. Boyce.
Horn Auto Supply Co., Omaha, Neb.; \$25,000; to deal in automobiles and accessories; Charles E. Fanning, F. J. McShane, Jr., William H. Horn.
Renton Auto Tire Company, Renton, Wash.; \$4000; Hugh B. Campbell, James L. Morfoot, Jesse F. Spurgeon, Joe Wood.
Sullivan Automobile Company, South Charleston, O.; \$5000; F. J. Sullivan and others.
Motor Service Company, Washington, D. C.; \$15,000; Thomas J. Raumstine and others.
Davis-Sparger Auto Company, Nashville, Tenn.; \$5000; Daniel Murray, Marlon M. Clish, George L. Grant.
Waterhouse-Sands Motor Company, Seattle, Wash.; \$100,000; Frank Waterhouse, P. E. Sands, Joseph Waterhouse.

GARAGE AND DEALER.

James Bennett, Rippey, Ia., has bought the business of the Graham Auto Company.
George H. Wike and **Edward Keller**, Barry, Ill., have entered the trade there. They will handle Maxwell cars.
Edward Coffey, Plattsburg, N. Y., has opened a new auto supply and repair shop at 67 Clinton street.
S. W. Wexler, general manager of the United Auto

Supply Company, New Orleans, La., will open an accessory store in Tucson, Ariz.

The Tyler Automobile Company, Pueblo, Col., agent for the Overland cars, has opened headquarters with the Owens Automobile Company at Sixth and Court streets.

Alexander C. Sutherland, Goshen, N. Y., formerly deputy county clerk, has entered the automobile business in that city.

The Jawer's Auto Supply Company, Philadelphia, has opened an agency for tires, accessories and supplies.

The Brunn Carriage Manufacturing Company, Buffalo, N. Y., distributor for the Peerless and Hupmobile cars, has also taken the agency for the A. V. shock absorber.

L. C. Lessenich, Sioux City, Ia., owner of the Pioneer Automobile Company, has sold his stock to S. C. Brown.

George J. Bohan, Sacramento, Cal., representing Cuyler Lee of San Francisco, has opened headquarters at 3308 K street.

Mankin & Connell, Philadelphia, Penn., has opened a magneto service station at 1416 Vine street.

A. H. McGraw, Syracuse, N. Y., who has handled bicycles and motorcycles for over 22 years in that city, has taken on automobiles. He has secured the Metz agency and will continue at his former location on West Jefferson street.

A. Hanton Chace, Los Angeles, Cal., has taken the agency for the Acme Torsion springs at 1044 South Olive street.

William Faatz, Oswego, N. Y., owner of the Binghamton garage, has leased a building on North avenue and will open a salesroom for automobiles.

Allen & Hardy, Monticello, Ark., has opened an automobile supply store.

Haley & Sheraton, Everett, Wash., distributor for the Ford cars, will purchase the business of the Ferrell Auto Company. The concern will also handle the Buick and Cadillac cars.

The Hartford Automobile Exchange, Hartford, Conn., will deal in second hand cars. The company is located in the Hartford National Bank building.

The M. & M. Sales Company, Reading, Penn., has taken the agency for the Prowodnik tires.

Bradley J. Saunders, Birmingham, Ala., formerly interested in the East Lake Land Company, has entered the automobile business, having taken over the agency for the Hudson cars. A company has been formed by him to be known as the Saunders Motor Car Company, and will be located at 422 South 20th street.

The Oregon Garage & Supply Company, Greenwood, S. D., has opened for business in the old quarters of the Greenwood garage on Maxwell avenue. O. M. Dantzler is president of the company and A. H. Jennings is manager. The company has the agency for Buick and Chevrolet cars.

The Western Motor Supply Company, Milwaukee, Wis., is the name of a new automobile firm located at 408 Jefferson street. The company will handle all lines of automobile, motorcycle and cyclecar supplies, and act as a jobber of automobile equipment as well.

The Bacon Wain Motor Sales Company, Toledo, O., has established salesrooms in a building at 1017 Jefferson avenue. The company is agent for the King, Empire and Pullman cars. It will also retain a repair shop at 840 Dorr street.

The Fisher Automobile Company, Indianapolis, Ind., has taken the agency for Hess-Bright ball bearings and will also handle all of the renewal business.

The Delancy-Cope Tire & Rubber Company, Kansas City, Mo., is the name of a new tire firm located there, and quarters have been obtained at 407 East 15th street. The firm will be the local distributor for the Motz, Portage and Polack tires.

Newell & Eccles, St. Louis, Mo., has opened offices and salesrooms at 3104 Locust street, where it will do business as agent of the Empire gasoline economizer.

The Goodby-Rankin Company, Providence, R. I., announces that it has obtained the services of William G. Rankin, who formerly had charge of the automobile supplies department for Belcher & Loomis of that city.

The Jeffery Auto Sales Company, San Francisco, Cal., announces that its new display rooms at the service building, 56-72 12th street, are now in first class condition. The entire line of cars is shown here, and to much better advantage.

WITH THE MANUFACTURERS.

The Detroit Steering & Windshield Company, Detroit, has changed its name to the Metalwood Manufacturing Company.

The Crown Motor Car Company, Louisville, Ky., manufacturer of the Crown cars, is planning to remove to Hamilton, O.

T. A. Hoover and E. G. Parsons, Fresno, Cal., have formed a partnership and the company will be known as the Hoover-Parsons Spring Company, to manufacture springs for automobiles.

The Pacific Kissel-Kar Branch at San Francisco, Cal., held an automobile show recently. The occasion was the opening of the company's new service building, the largest on the Coast.

The Paige-Detroit Motor Car Company, Detroit, maker of Paige cars, has opened its new factory. The main building is 816 feet long and 60 feet wide, three stories in height, and there is a wing of 120x60 feet. One of the unique features of this new equipment is that occupancy is had without one dollar to be paid out of the profits of the cars built in the future.

The Portage Rubber Company, Barberton, O., has decided to build an addition to its plant at a cost of \$25,000.

The White Company, Cleveland, O., maker of White pleasure cars and trucks, was recently the "victim" of a pleasant surprise party, when 84 merchants, bankers, lawyers, farmers and men in other walks of life from

has leased three buildings in Newark, N. J., which, when equipped, will be utilized for the manufacture of storage batteries. The buildings acquired were a part of those which at one time were occupied by the Titan Steel Works. Henry Keith of New York is president of the company.

The H. Lund Smith Company, Paterson, N. J., manufacturer of windshields, tops and other equipment, has purchased the plant of the Paterson Manufacturing Company of that city. The latter concern manufactures leather and fabric novelties, and the acquirement of the plant will permit the H. Lund Smith Company to produce slip covers, hood and tire covers and similar specialties.

The Electric Auto-Lite Company, Toledo, O., engaged in the manufacture of electric starting and lighting devices, has increased its capital stock from \$100,000 to \$225,000.

The U. S. Ball Bearing Company, Oak Park, Ill., announces that since Jan. 1 the product of the company is being marketed by its own sales force, with headquarters at the home office in Oak Park. The company had been represented by Denton & Flagg.

The Lyons-Atlas Company, Indianapolis, Ind., has issued the Lyons-Atlas News, which will be published as a regular house organ by the company. It is well edited and contains a number of articles of interest to dealers and owners of Lyons-King cars.

The Presto Inter-Rim Company, Boston, Mass., has made arrangements with the Cleveland Welding & Man-

Delegation of Iowa Men Which Recently Tendered the Officials of the White Company, Cleveland, O., a Novel Surprise Party.

Des Moines and Oskaloosa, Ia., in charge of O. F. Shee, Central Iowa distributor for White products, arrived at the factory in two special railway cars. The officials of the company soon recovered from the surprise sufficiently to escort the party about the plant, show them everything there was to see, and get them to pose for a picture, which last named is reproduced herewith. In addition, they were entertained by a tour of the city in White omnibuses, and by a luncheon at the Cleveland Athletic Club.

The Hyatt Roller Bearing Company, Newark, Detroit and Chicago, is distributing a handsome folder, containing a reproduction of Sun Yat Sen, provincial president of China, and Vice President Drake of the Hupp Motor Car Company, Detroit, in a Hupmobile on the streets of Shanghai, China. Of course, attention is called to the fact that the car in question is fitted with Hyatt roller bearings.

The Maccarr Truck Company, Scranton, Penn., which moved recently from Allentown, where it had been operating since 1904, is having new and up-to-date machinery installed in its new manufacturing plant recently completed.

The McCormick Manufacturing Company, Dayton, O., and the Eastern Machine Screw Corporation, New Haven, Conn., have taken out spark plug licenses under the Canfield patent, held by A. R. Mosler & Co., Mount Vernon, N. Y.

The Titan Storage Battery Company, Baltimore, Md.,

manufacturing Company, Cleveland, to manufacture the Presto rim. The Cleveland company was one of the pioneers in the rim field, and is equipped to build the Presto rims in large quantities. The Presto Inter-Rim Company has also closed with the American Distributing Company, Jackson, Mich., to handle the sale of the rims in the West.

The Timken Roller Bearing Company, Canton, O., has found it necessary to build a large addition to its plant. The new structure is one story high, with a ventilator above its centre for light and ventilation.

The Doehler Die Castings Company, Brooklyn, N. Y., recently made arrangements for a branch factory at Toledo, O., and already has found it expedient to double the capacity first provided for in the plans. Instead of only having 10,000 square feet, the new structure will provide 20,000 square feet, under the general management of H. B. Griffin, vice president of the company.

The Wasatch Motor Manufacturing Company, Salt Lake City, Utah, will erect a factory on State street, for the manufacture of its trucks.

The République Rubber Company, Youngstown, O., maker of the well known Republic Staggard Tread tires, has recently placed upon the market a tire designed especially for the Ford cars.

The Way Muffler Company, Philadelphia, Penn., is considering the establishment of its plant at Wilmington, Del. The company has taken the matter up with the Chamber of Commerce.

STANDARD CHARGING PLUG.

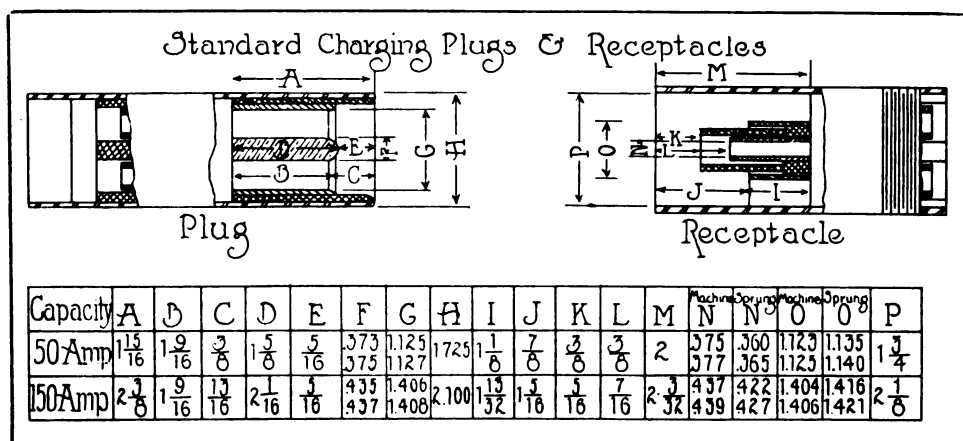

Two Sizes, Outside Contact Positive, Approved by Electric Vehicle Association.

For the benefit of all who may be in any way interested the Electric Vehicle Association of America is distributing a specification sheet showing a detail sketch of the standards for charging plugs recently approved by the organization. Those familiar with electric vehicles understand the value of this information, but for the benefit of those who may not be informed the explanation is made that the charging plug is the terminal of the cable lead from the line carrying the current, and is a permanent fixture. All vehicles are fitted with a receptacle, so-called, which is connected with the wiring of the battery and the operation of charging is practically automatic when the charging plug is fitted into the receptacle. But efficient transmission of energy is only practical where the contacts are good and the charging plug fits the receptacle. Until the present time charging plugs and receptacles have not been uniform. A charging cable and plug is not generally carried, and when in the event of emergency a supplementary charge is necessary if the plugs of the cables will not fit, or fit imperfectly, the receptacles of the vehicle, a situation results that is exasperating, if not serious, and when applied to a service machine may be discouraging.

A standardization committee of the association carefully considered the problem, and in communicating with manufacturers of vehicles found that out of 20 replies 13 were using a concentric type plug. Of this 13 nine made the centre terminal negative, and five manufacturers made the centre terminal positive. In view of the facts ascertained the committee recommended that the association approve a plug with the outside terminal positive and the inside negative.

The specification sheet shows that the committee recommends two standard sizes, the smaller of 50 amperes capacity for pleasure cars, and the larger of 150 amperes capacity for trucks,

either to have a 50 per cent. overload capacity. The detail dimensions are set forth in a tabulation. The National Board of Fire Underwriters has approved plugs of the dimensions given. The association's committee has recommended that the terminals should be large enough to receive cable having a rating, according to the Underwriters' Code Table B, at least equal to the normal rating of the plugs, and that the terminals should be marked plus and minus to correspond to the polarity of the plugs. The committee is now distributing these sheets to all persons interested, to manufacturers, owners and charging stations and garages, urging the prompt adoption of the standardized plugs and receptacles, and the change of polarity, both on old and new vehicles, and charging equipment, to bring about a desired uniformity. The belief is, that when the standard has been adopted and the change made as suggested, electric vehicles can be

The Detail Drawings and Dimensions of the Charging Plugs and Receptacles Approved and the Use Recommended by the Electric Vehicle Association.

charged anywhere that electric current is made, and all delays or complications will be eliminated.

The Adamson Manufacturing Company, East Palestine, O., is calling the attention of the trade to the recent decision of Judge Dyer in the United States district court for the eastern district of Missouri, sitting in St. Louis, in the action brought by this company against the Gilliland Auto Supply Company of St. Louis, alleging infringement of the Adamson patent on vulcanizers. The decision was for a decree and permanent injunction, and the company maintains that this covers vulcanizers constructed to retain a combustible fluid which is heated simultaneously with the vulcanizer by the combustion of the fluid, and the temperature is thereby automatically controlled.

BUICK ECONOMY TESTS.

Four and Six-Cylinder Models Undergo Interesting Trials in Chicago.

With Chicago newspaper men and technical automobile writers as official observers, and F. E. Edwards, formerly chairman of the American Automobile Association's technical committee, as conductor, the Buick Six and B-25, made by the Buick Motor Company, Flint, Mich., were submitted to gasoline consumption tests in Chicago, Jan. 14. The six-cylinder model made 20.1 miles to the gallon and the four-cylinder 22.7.

The conditions of the test required that at no time should the clutch be thrown out. The weather was a mixture of snow, sleet and rain, and the temperature was about 45 degrees Fahrenheit, and at the finish 27 degrees. More than one-third of the distance was covered against the wind, which, according to the government weather bureau, was blowing 23 miles an hour.

Inspector Edwards examined the cars to satisfy himself and the committee that everything was standard, and also made a test of the gasoline to determine that it was of standard grade. After the completion of the runs, the cars were weighed with the passengers, and again inspected by Mr. Edwards. They were then driven to the Stewart-Warner Speedometer Corporation's headquarters, where certificate was given as to the correctness of the speedometer.

SECOND PITTSBURG SHOW.

Seventy Makes of Pleasure and Commercial Vehicles in Exposition Hall.

The first 1914 Pittsburg automobile show having passed into history, it is in order to note that the second display in that city will be held in Exposition hall, Feb. 14-21. Officially, this is designated as the fourth annual automobile and truck show of the Pittsburg Auto Show Association. J. H. Zimmerman is manager.

From the advance announcements, it would appear that in point of number of exhibitors, at least, this second exhibition will be larger than the first. Already 70 makes of pleasure cars and trucks have been entered. In one respect, however, if the statement of the management be accepted, this display will set a new record for America. Twenty different makes of cyclecars are promised.

The decorative treatment will be entirely new, some 10,000 feet of continuous paintings

having been secured with which to drape the walls. The electric equipment will require 300,000 bulbs, which will be festooned about the interior. Additional space will permit of an enlarged accessory department, and every effort will be made to present the biggest and best show western Pennsylvania ever has known.

RAD-FIX RADIATOR COMPOUND.

A Filtered Chemical Solution for Repairing Leaks in the Cooling System.

Rad-Fix is manufactured by the Radiator Fix Company, 121 Massachusetts avenue, Boston, and as the name implies, it is compounded to repair leaky radiators. One of the qualities emphasized in it is that it is a filtered solution and will pass easily through the screen of the radiator. It is a chemical solution and the maker states that its action on lead, copper and brass causes crystallization of the metals on the outside of the radiator, forming a permanent weld.

It is left in the cooling fluid and is held to possess cleansing properties as well as to improve the cooling. Rad-Fix is stated to boil at 260 degrees Fahrenheit, considerably above water, an advantage in service on mild days, and to freeze at 26 degrees, six below that of water. Rad-Fix is sold in gallon cans and is accompanied by a strong guarantee.

Secretary-Treasurer G. B. Gibson of the Federation of American Motorcyclists, reports that 168 new members were secured during the month of January, classified according to states as follows: Illinois, 25; New York, 21; Pennsylvania, 20; Iowa, 14; Ohio, 13; Indiana, 13; New Jersey, seven; Florida, six; Georgia, six; Kansas, six; Arizona, four; Maryland, four; Nebraska, three; Oregon, three; New Hampshire, District of Columbia, Texas, Wisconsin, Michigan and California, two each; Maine, Massachusetts, Rhode Island, North Carolina, Alabama, Oklahoma, Missouri, Minnesota, North Dakota, Washington and the Philippine Islands, one each.

The Lincoln Highway Does not pass through my town

Why should I worry about the Lincoln Highway? I'd have to drive about 300 miles to get to it, and such a thing as devoting the time and money for a long tour is beyond me.

A Question:

Why should I contribute my little mite to this great Ten Million Dollar enterprise? I am not a sport. I am just an ordinary individual, clothing and feeding a moderate family and educating my children. By plugging hard six days in the week I am able to keep out of debt and keep money enough in the bank to buy a new tire occasionally. About the only diversion I have is romping with the kids and piling them and the good wife into the back of the machine and hiking out for a short ride in the country in the late afternoon. Dad is fortunate enough to own an old car and able to buy gasoline enough to keep it going.

The Answer:

Just the same, I am mighty glad if the little \$5 I can pinch out of my earnings will help make it a success. I expect to live several years yet, and I never expect to be without a motor car. I have been dreaming of the time when all our roads will be good, when I can drive 20 miles into the country without accumulating a bunch of expense for repairs. In a word, I want good roads and I want them so badly I can taste the desire. I know that when the Lincoln Highway is put through it will not be five years until every road of consequence in this broad land is a good road. It will spread a whole network of good roads. I will be personally benefited just as if it passed my door.

An Argument

Do you want cheaper hauling of farm products? Do you want a lower cost of vegetables, meats, everything that goes on your table? Do you want a more prosperous land to live in? If you want any of these things you want good roads, and in all the agitation for good roads there has been no movement that carries with it so much of promise for the immediate future as this Lincoln Highway.

Send your contribution to this patriotic cause TODAY to

Cut out the Oil Lamp Nuisance

Get rid of the bad-smelling, old-fashioned oil lamps. Every time you want to light your oil lamps you have to get out of your car.

You can light all lamps right from the seat when your car is equipped with

JM MOBILITE ELECTRIC LAMPS

These lamps operate on dry batteries, and cost about one-third as much to install and only one-third as much to operate as standard electrical equipment. Will burn from 300 to 420 hours on six 30 amp. J-M Dry Batteries. Used for head lights, dash lights, tail lights, speedometer lights and interior car illumination.

Order from our nearest branch if not at your dealer's.
Write nearest Branch for Booklet

BUYING AND SELLING MADE EASY

15,000 Trade Interests

READ THE

Accessory and Garage Journal EACH MONTH

You can secure your monthly audience with all buying and selling heads in all concerns in every branch of the automobile industry through the Accessory and Garage Journal. Such interests must know what you have to offer. All are logical prospective purchasers. They constitute your market and are always looking for lines of merit.

In this magazine the large and small manufacturer has equal opportunity to reach the whole trade and can secure a service equal to that of a trade mailing list and better than can be secured through any other medium.

100 Per Cent. Quantity—100 Per Cent. Quality—Circulation Value.

Every order carries with it a positive guarantee of service stated, and this in any form requested.

Ask how we give concern and product listing under proper classification in Buyers' Guides that have a distribution of more than 1,100,000 copies yearly. This service is free. Our trade mailing list is 100 per cent. active—Do you need it? Details gladly furnished on request.

THE AUTOMOBILE JOURNAL PUBLISHING COMPANY
Times Building Pawtucket, R. I.

"The Government insists that Railroads maintain fair and equal rates for all. Why should not manufacturers also have the right to maintain their prices?"

DETROIT, MICH. U.S.A.
October Seventeenth,
1913.

CFT-GB.

Mr. T. J. Daley, Sec'y,
Standard Woven Fabric Co.,
Framingham, Mass.

Dear Sir:-

On account of the satisfactory results obtained from tests of the Multi-bestos Brake Band Lining we have signed, and are enclosing herewith, our contract for 150,000 ft. which is our approximate requirements for one year.

Respectfully

Packard Motor Car Company.
C. J. Tollgen
Purchasing Manager

Why

The Chart shows the results of a series of tests conducted for us at the Worcester Polytechnic Institute to determine the relative superiority of Multibestos over five other leading brake linings. Just exactly how much superior Multibestos is in various braking qualifications is shown by the chart.

The figures from 0 to 36 represent units of pressure on the brake pedal. Figures from 0 to 100 represent the braking effect on the car wheel.

So, taking 16 units pressure, Multibestos shows a braking effect of 57; the other linings from 48 on down to 26 or from 85% down to 45% of the efficiency of Multibestos.

Insure the safety of the cars you sell by seeing that they are Multibestos equipped.

PANHARD OIL

Carelessness Is Expensive

Probably you are tired of hearing about oil. All oils look about alike, regardless of price. How can there be any great difference in quality? Besides, the really good grades carbonize just as much as cheap ones, unless they are properly used.

BUT—If you need new bearings after a season's run, the repair bill hurts, doesn't it? Probably you blame the bearings or the car manufacturer or your repairman, though almost always the fault is simply poor lubrication. A little care at the start would have avoided it.

PANHARD OIL is refined from Pennsylvania crude. It is thoroughly filtered and purified. It has a heavy lubricating body at high temperatures. It will practically end bearing troubles. Your dealer has it or will get it for you. Send for our new booklet, "The Oil Question", now.

MR. OWNER MODEL T FORD CAR:—If your coil is getting old, not working as it should, or has been damaged, send it to us and we will promptly make an exchange with you, and give a brand new, guaranteed coil, perfect in every particular, and one of our regular Ford T Specials.

Our allowance will be the same on every coil received and the exchange will be on one basis for one or 100 coils. Get our price---You will swap and do it quick. You can't even afford to think of repairing your old coil.

MR. DEALER:—Get your old coils together. Write us the number and we will do the rest. All coils carry our regular guarantee. Make your sales and replacements accordingly. You receive such an offer once in a lifetime. It will make business and money for you and satisfy your customers.

WE RESERVE THE RIGHT TO WITHDRAW THIS OFFER AT ANY TIME

CONSTRUCTIONAL DETAILS OF THE TYPE B-52-6 COIL, FOR MODEL T FORD CARS

The Heinze coil is specially designed to operate with the Ford Flywheel Generator. Owing to the special windings, vibrator and general construction, we guarantee its efficiency when used in conjunction with the Ford Flywheel Generator only.

Vibrator is rapid and positive in action, assuring a volume of sparks at the highest points of compression. The magnetic pull on our vibrator is intensified by our patented magnetic shields. This means a more violent interruption of the primary current, and, as the efficiency of the secondary depends on the interruption of the primary, the superior efficiency of this coil can easily be understood.

Our method of winding not only gives a hot spark, but the special balancing gives unlimited service without pitting or burning of the platinum points. This obviates the necessity of readjusting. Our units will start the motor with less cranking than any other coil made and are much more efficient and smoother running than any master vibrator.

The Heinze coil consumes less current than any other coil made, making possible the use of two 16 candlepower electric headlights in series with the flywheel magneto circuit, and without interfering with the efficiency of the coil.

The Heinze coil will operate at any engine speed of from 200 to 2000 revolutions a minute, at any position of the adjusting nut, as the new adjustment is limited to two and one-half turns and is absolutely fool proof.

FOX AUTO SEARCHLIGHT

The
Control
That
Prevents
Road
Accident

The
Control
That
Shows
All
Dangers

Cut Showing Fox Light Attached to a Demonstrator Car of the Fox Auto Searchlight Co.

THE LIGHT THAT NEVER FAILS

Independent action of either lamp is shown by position of right light.

The FOX AUTO SEARCHLIGHT converts your fixed lamps into road searchlights. No New Lamps Required, all moving parts are inclosed and there can be absolutely no rattle or vibration. IT IS A THOROUGHLY TESTED, PRACTICAL EQUIPMENT, easily installed, and it improves the appearance of any car. The FOX AUTO SEARCHLIGHTS are a necessary protection for the motorist and for all users of the road, furthermore a comfort and great convenience for every one driving at night.

The device illuminates the curves and corners automatically. It illuminates the sides of the road, showing the driver persons, crossings, bridges, obstructions, washouts, etc., which with the present auto lamps cannot be seen on curves. In addition the lamps may be instantly controlled by hand from the driver's seat independent of the steering gear, so as to throw the light across curves or corners before reaching them, or if desired, to illuminate in this manner ruts, ditches, washouts or other obstructions by the side of the road, to find cross road signs, street names, house numbers, etc., or to deflect the glaring light when passing another car—every motorist knows how all important this is.

DRIVERS MUST SEE BEFORE THINKING AND ACTING

From the standpoint of safety you can no more afford to be without the Fox Swivelling Headlights than without the horn which sounds the warning—both are essential to safe travel.

THE INVENTION WHICH IS PROTECTED BY STRONG BASIC AMERICAN AND FOREIGN PATENTS IS MANUFACTURED BY EXPERT WORKMEN AND BY UP-TO-DATE MACHINERY, IS MADE FROM THE BEST MATERIAL AND IS GUARANTEED TO GIVE ENTIRE SATISFACTION. The great value of the device makes it an easy seller. Auto owners can develop a remunerative business in connection with regular use of their machines by demonstrating the Fox lights.

A FEW GOOD REGULAR AGENTS ARE WANTED, TO WHOM DEMONSTRATION EQUIPMENTS WILL BE FURNISHED AT A NOMINAL PRICE.

WRITE OR WIRE FOR AGENCY PROPOSITION. YOUR TERRITORY MAY BE OPEN.

FOX AUTO SEARCHLIGHT CO., 78 Fountain St., Providence, R. I.

A Demonstration car equipped with Fox Auto Searchlights will be shown at our stand, No. 325, at the Boston Show, March 7 to March 14, 1914.

Garage Soap Economizer

Reduces soap consumption **one-half—Saves all waste—Prevents theft.**

Simply fill with four to six pounds of soap, suspend by chain or cord in water washing tank or barrel.

TWO-IN-ONE OFFSET GASOLINE FUNNEL

With Fine Brass Strainer, Movable Hoop to Hold Chamois. Spout easily removed, thus forming a regular funnel.

HEAVILY COPPER PLATED.

Galvanized Garage Funnel

First practical Garage Funnel of large capacity (10 qts.) at a popular price.

The Strainer of re-enforced 100 mesh Brass Wire Cloth, is removable, to prevent breaking, can be easily replaced and is of a new cone shape, a great advantage in giving a larger straining surface, and tending to prevent dirt and water from being forced through.

When Writing to Advertisers, Please Mention The Automobile Journal.

EAGLEINE OIL

is the

Better Oil

The reputation of Eagleine No-Karbon Oil as the best oil in America for water-cooled cars, has not been gained by extravagant advertising or loud shop talk by salesmen, but by the large and ever increasing number of users, who unsolicited have testified to the wonderful results attained by the use of our oils.

BELOW WE PRINT ONE TESTIMONIAL FROM OUR FILES:

Eagle Oil & Supply Co.,
Boston, Mass.

Cambridge, Mass.
Feb. 9, 1914

I shall send you tomorrow by Savage & Sons' Express an order for your Eagleine No-Carbon Cylinder Oil, suitable for my 4 cylinder Stevens-Duryea motor. Please send bill to me direct.

A friend coaxed me away from you, but carbonized spark plugs, and engine trouble drove me back.

Yours truly,
Albert S. Parsons.

May we not send you our booklet describing this oil, and a copy of several letters from our enthusiastic users?

GRAY & DAVIS

STARTING-LIGHTING SYSTEM

FOR FORD CARS

Gray & Davis announce a starting-lighting system for FORD cars. This new system is very compact, and can be installed in a few hours by any garage man or automobile mechanic. It is extremely simple in design and construction and possesses GRAY & DAVIS quality in material and workmanship.

Gray & Davis Ford System Includes Edison Battery

To Ford Dealers

Every prospective and present owner of a FORD will be interested in this starting-lighting system. We believe there will be a very great demand. We suggest that you write for our proposition to Ford dealers.

GRAY & DAVIS, Inc.

Boston, Mass.

J. H. S. SHOCK ABSORBERS

are a revelation as well as a revolution in spring suspension.

Their sensitiveness of action **AUTOMATICALLY** takes up and destroys jars and jolts, either heavy or light, and to the occupant of a car it seems like riding on air—fairly floating through space.

Vibration is eliminated, thus giving long life to tires, motor, transmission and other components. In consequence greater speed is possible, as the car does not tend to skid or roll. The mechanical principle of the J. H. S. Shock Absorber is as scientific as that of a hydro-carbon engine. A cylinder and piston are used to insure durability, there being no fragile parts to wear or easily get out of order. The piston acts in harmony with coiled springs which destroy all shocks.

\$485 The Salvador Cyclecar \$485

MOTORCAR VALUE AT CYCLECAR PRICE
PLAZA MODEL
BOULEVARD-ROADSTER TYPE

Salvador has arrived a little late, but is moving fast in the streamline of quality.

The advent of The Salvador Cyclecar marks the finish of two years investigation of small car conditions in Europe and America.

The Salvador Car is designed by G. B. Mansur of Boston, who has been identified with manufacturing and selling of automobiles for 12 years. Mr. Mansur's association with The De Dion Bouton Co., of Paris, and his varied experience in American manufacturing, has enabled him to embody the best of European Cyclecar Models in The Salvador Cyclecar, to meet the practical requirements of the American Trade.

His beautiful Luxembourg exterior design in The Plaza Model meets every requirement of quality trade.

***Four Cylinder Water Cooled Engine,
 Selective Transmission, Shaft-Driven
 Car Is the Answer to Practical Cycle-
 car Requirements.***

Salvador Specifications insure the owner the utmost in motoring combined with all the comforts and refinements of a high priced motor car.

NOTICE TO DEALERS

The Salvador Motor Co. plans a limited output for 1914. Absolute deliveries to begin April 10, 1914. Correspondence and bids for territory solicited. The Salvador Motor Co. gives an absolute guarantee covering material and workmanship on the Salvador Cyclecar.

SPECIFICATIONS.

MOTOR—4-cylinder, 4-cycle, 15 horsepower, water cooled, L head 70mmx100mm. Cast enbloc.

LUBRICATION—Self-contained, constant level splash and force system, plunger pump operated by camshaft.

COOLING—Water cooled, thermo-syphon system.

TRANSMISSION—Unit, with motor, crucible steel gears, double heat treated, oil hardened, running on ball bearings, three speeds forward, one reverse.

CLUTCH—Simple cone clutch, three-spring adjustable type.

FRONT AXLE—Tubular, with drop center, conventional type.

REAR AXLE—Bevel gear drive, patented non-skidding differential.

STEERING GEAR—Worm and sector type, with 15" steering wheel.

FRAME—Pressed steel, channel section.

SPRINGS—Front, $\frac{1}{4}$ elliptic; rear, cantilever.

WHEELS—Wire, 28x3 tires.

WHEEL BASE—100" wheelbase, 42" tread.

CONTROL—Left hand drive, center control.

GASOLINE—Gravity feed tank, located under cowl.

BODY—Luxembourg design; boulevard-roadster type, streamline effect; Staggered seats with ample leg room; luxurious upholstery; parcel compartment in the rear.

SPEED—45 miles per hour. Plaza model, 65 miles per hour.

FINISH—Deep purple, black trimmings.

Atwater Kent Ignition

What Two of Thousands of Owners Have to Say

"Smoothest Running Motor I Ever Used Since I Replaced My Magneto With the ATWATER KENT SYSTEM."

"No trouble in starting in the coldest of weather, and can start on the spark. Have run 2100 miles on one set of batteries and they are still doing the work. Not a skip or a miss even when throttled down to a walk and on the high gear. As for power, I can climb hills on the high that made me drop to the second with my old ignition system. Am getting more mileage to a gallon of gas.

"I changed over to the ATWATER KENT SYSTEM because it is simple, first cost covers all costs, needs no adjusting like magneto breaker boxes and because I could install and time it.

"Since buying the ATWATER KENT SYSTEM I figure I have saved its cost in fuel alone, to say nothing of back breaking work I used to have when starting with the magneto system.

"My 1914 car is going to be ATWATER KENT equipped even if I have to put it on myself. It is the one satisfactory, economical system that you never have to think about after you put it on the car. That's comfort."

"Effects A Gain of 10% In Speed And Hill Climbing Ability Of The Ford."

Magneto Mounting.

"Your type F Unisparker outfit with attachments for Model T Ford car has been carefully installed on my car, and I would like to take this occasion to express my pleasure with the performance of this outfit.

"Formerly I had the four vibrating coils and timer which came with the car, and which derived its current from the regular Ford magneto. You know the troubles incident to a vibrating coil and timer outfit; and I decided to install one of your Unisparkers, with which I have had considerable experience in the past.

"Since installing your outfit I have gained approximately 10 per cent. in speed and hill-climbing ability, together with a sweetness of running which is a revelation to me in this particular car.

"This makes a nice combination for a Ford; inasmuch as I now use the entire magneto ability for operating electric lights and the ordinary dry cells for my Unisparker System.

"I am getting another car soon, and will also expect to install this same outfit in the new car as soon as it is delivered."

Ford Equipment.

Time and space prevents the publication of hundreds of other testimonials from which the above were selected. If you are interested in ignition it is worth your while to write for a copy of our Booklet L.

1000 Car Loads

For One Dealer

WE have one dealer who takes 1000 car-loads of Overlands every twelve months.

That's 5000 cars.

This dealer wired us a few months ago and wanted 7000 cars, but we could not supply them.

Other dealers take 2500, 2000 and 1500 Overlands apiece.

Even the 1500-car dealer takes more cars than the largest single factory in Germany turns out.

There are over 200 American automobile manufacturers who do not make in a year as

many cars as our one single 5000-car Overland dealer takes in the same period.

If you think this over for a moment these figures will mean something to you.

It certainly is reasonable to assume that we must be giving more car for less money than any other manufacturer in the business.

If we were not, we could hardly be doing the largest business.

That's sound logic.

If you will just take the time to make a few specification comparisons you will find the cost of the Overland is 30% less than that of any other similar car made.

Our catalogues will be sent on request. Please address Dept. 52

MANUFACTURERS BOSTON, MASS.

Cars, Like Men, are Known by the Company they Keep

The Metz "22" is probably the least-known car in the repair shops—and this speaks volumes in few words. It is so practical in design and so compact in construction that it easily over-rides the bumps and the road-wear that send other cars to the repair man. Confirmation of this claim is supplied generously by the result of the recent Glidden Tour, which was a clean sweep for the Metz.

Equipped Complete—1914 Improvements

METZ "22" \$475

The GEARLESS CAR—No Clutch to Slip, No Gears to Strip

In addition to being the lowest priced car on the market, the **METZ "22"** is the most economical in operation and up-keep. It will travel from 28 to 32 miles on one gallon of gasoline, 100 miles on one pint of lubricating oil, and from 10,000 to 12,000 miles on a single set of tires.

The **METZ** team of three cars was the **only** team in the recent Glidden Tour, from Minneapolis to Glacier National Park, Mont., to hold a **perfect score**, without ad-

ditional allowance or time extension of any kind, for the entire eight days of the contest.

The **METZ "22"** is a fully guaranteed car, with standard equipment, including 4-cylinder 22 ½ h.p. water-cooled motor, Bosch magneto, 30-inch artillery wheels, best quality Goodrich clincher tires, etc., etc., complete—no "extras". It makes from 5 to 50 miles per hour on the high speed, and its gearless transmission does away entirely with gear troubles.

We want a Representative in every City and Town. Write for Terms and Catalog "Q".

METZ COMPANY - WALTHAM, MASS., U. S. A.

CAN YOU START YOUR MOTOR ON THE FIRST TURN?

The Duelec Vaporizing Primer

MAKES IT POSSIBLE

With the Duelec, in zero weather, and with any kind of fuel—gasoline, kerosene, denatured alcohol, etc., the fuel is supplied to the cylinders in a hot, fuming, vaporized form, exploding with the first spark.

ALL YEAR NECESSITY

December as in June

Low grade fuel nor cold weather can bother

OUR OFFER:

Send \$2.00. We will forward a DUELEC for trial. If after 10 days you are not

convinced of its all around superiority over any similar device (regardless of cost), return and we will refund deposit. If highly satisfied, send us balance due, \$3.00.

WHAT THE DUELEC DOES

The principle of the Duelec is right. It raises the temperature of any fuel to a point where it vaporizes quickly, and mingling with the air provides a homogeneous mixture, one that will start the motor on the first turn, and in any kind of weather. The Duelec heating chamber is scientifically constructed, and by the use of a resistance coil heated by electricity, the fuel is converted into a fuming mist. This is drawn into the cylinders and exploded on the first spark. The Duelec is operated by any source of supply of current and consumes but a small amount.

Anyone can attach the Duelec in a few minutes. It is placed above the carburetor, and two wires lead to its terminals. It will operate on any six or twelve volt battery, etc., or on the Ford magneto. We supply resistance coils or heating chambers for any standard voltage. The Duelec is particularly adapted to cars using motor starters as it saves the battery. Owners of Henderson cars and others using heavy fuel can eliminate the gasoline supply by using a Duelec.

DEALERS---The best proposition on the market. Heavy demand assured on account of low price, and all-around superiority.

MANUFACTURERS OF STARTERS---Duelec included as part of equipment stamps A No. 1 efficiency on your primer, and converts it into an article worthy of the name, **STARTER.**

AUTOIST, AVIATOR, MARINER---Demand the Duelec from your dealer. If he cannot supply you, write direct, giving size of supply line, current voltage. If for Ford, whether to operate from the magneto or batteries. We fill orders for 1-4 inch supply line and for six volts unless otherwise specified.

PRICE \$5.00.

WADDELL

Say Good-by to your chains when you use the "Columb" tread

Russian engineers first worked out the counter-cross or reverse herringbone pattern *theoretically*, as a tread which *could not skid*. Then it was tried out practically on the steppes of Russia, over the smooth roads of England, in the mountains of Switzerland and Spain.

It was used on every type of car and under the severest conditions imaginable. *It worked; it would not skid*. It is one of the features which quickly made known throughout the world the name of the

PRO-WOD-NIK Columb Tread Non-Skid Tires

Pro-wod-nik Tires are quality tires, built on the principle that "the best is the safest and the cheapest" in everything pertaining to the running of a car. On the Continent and in Great Britain they are known to and preferred by every owner of a high grade car.

Pro-wod-nik Tires have a resiliency greater than that of any American tire. Every ply of fabric used in their construction is impregnated, by a special process, with pure Para, which gives the core the same elasticity as the tread. A layer of pure rubber compound between each ply of fabric binds the fabric together and further increases the *universal resiliency* of the tire. The side walls are of exceptional thickness and the construction of the bead is such that rim-cuts are unknown in Pro-wod-nik Tires.

Write for Booklet

Whatever make or grade of car you operate, you cannot afford not to know about Pro-wod-nik Tires. For safety and low mileage cost you will find them unequalled. Write for booklet and learn all about them.

Makes Good

That's the essential element. That's the verdict of the users of Colonial Oil. That's why they always say Colonial---because they know it's

"The Motor Oil that Makes Good"

Use COLONIAL and
NOTE the DIFFERENCE

COLO GREASE

A real transmission grease

Will make your gears run smoothly and quietly because it is made especially for gear lubrication.

COLONIAL Timing Gear Oil

overcomes all trouble with your timing gear. Use it and

NOTE the DIFFERENCE

SILEX GREASE

The greasiest grease made

The real test of a grease is not its looks or the feeling but its lubricating properties. Silex is made to lubricate and last.

The Qualities I
want in Top
material I can
get only in
Pantasote

"I want a good-looking material.

"I want a material that looks well after long service—
as well as when new.

"I want a top material that won't FADE or become
shabby.

"One that is waterproof and remains waterproof.

"One that won't crack, peel off or chip off.

"A Material unaffected by sunlight or temperature
changes or grease.

"I want a material that can be easily washed clean with
soap and water.

"And lastly, I want to know that the material is made
and backed by a company of long standing and
reputation."

BRAENDER TIRES

BRAENDER VICTORIES

De Palma's **BRAENDER EQUIPPED** Vanderbilt Cup Mercedes.

INDIANAPOLIS 500 MILES: May 30, 1913.—The first car that ever went through a 500 mile race *without a tire change* was Mulford's **Braender Equipped** Mercedes.

COLUMBUS 200 MILES: July 4, 1913.—Mulford in a **Braender Equipped** Mason broke the world's record by over 6 minutes, *without a tire change*.

ELGIN TROPHY, 301 MILES: Aug. 30, 1913.—Anderson in a **Braender Equipped** Stutz took **first place**. Mulford took **second** in a **Braender Equipped** Mason *without tire change*, using the same four tires that had already been through the Chicago Trophy, (301 miles), 100 mile race at Cincinnati, and 11 short races, making a total of **over 1100 miles racing on one set of Braender Tires**.

VANDERBILT CUP RACE, 294 MILES: Feb. 26, 1914.—DePalma took **first place** in **Braender Equipped** Mercedes, *without a tire change*, averaging 75.6 miles per hour. The Mercer, the Mason and the Stutz, all **Braender Equipped**, finished **second, third and fourth**.

GRAND PRIZE, 403 MILES: Feb. 28, 1914.—DePalma in a **Braender Equipped** Mercedes, takes **fourth**.

ASIDE FROM RACING:—Jack German's 22-passenger sight-seeing car operating in New York, is still using four **Braender Pneumatics** which have given over 6000 miles of service.

This is proof that **Braender Tires** excel in any kind of service.

A Good Winter Actor

Model 7—

Has no clutch to be affected by cold contraction.

Has no gear case filled with chilled and nearly frozen grease.

Gets under motion just as easily in winter as in summer.

Rolls along smoothly and quietly in any weather and on any roads.

Has the tremendous leverage of the gearless transmission to assist the sturdy pull of the four cylinder engine.

Has a speed to suit every case and equal to any emergency.

Has electric starting, light, horn and complete equipment of accessories.

Cartercar Model 7 is almost more than you would expect for the money.

Phone our nearest Dealer and he will call for you in a Model 7.

ROADSTER

The Car for the Nation

"More than a Cyclecar"

\$520
TOURING CAR

AS CATALOGUED

The Low Priced Car that in Design, Construction and Detail Ranks With Big Expensive Motor Cars

The Car-Nation is a car that any one would be proud to drive. It embodies all the "up to the minute" ideas in both European and American practice, while the price brings it within the reach of the great majority of buyers.

The light weight—great economy in operation—25-30 miles to the gallon of gasoline—ease of handling—low initial and upkeep cost—long life of the tires—speed and hill climbing qualities, make the Car-Nation unsurpassed for general utility.

There is nothing freakish about the whole car—every part is standard—four cylinder block motor—multiple disc clutch—3 speeds forward and reverse—selective type transmission—floating rear axle—wire wheels—left side drive—center control—in fact everything about the whole car has been approved as the best practice.

Dealers throughout the whole country can make a very advantageous agency connection by writing or wiring now.

The New "Six-48" Keeton

The Keeton has that distinctive French type of construction that has always made the strongest appeal to people of culture and refinement, both in Europe and America, as the criterion among motor cars.

The mechanical excellence of the Keeton and the completeness of the equipment insure the maximum endurance and comfort in use.

Write for "THE TRIPLE TEST" booklet.

Regal

The Distinctive Car for the Discriminating Buyer

THOUSANDS of Regal owners the country over will tell you that the exclusive Regal construction makes Regal cars the last word in safety, stability, comfort and economy.

Compare the Regal in these respects with cars at a higher price, if you will. But—and here's the real test—compare

the Regal with other cars at about the same price.

1914 bids fair to be far and away the biggest year in Regal history.

For the Regal is—and will be this year more than ever—the easiest bridge between the dealer who wants a satisfied trade and the buyer who wants a satisfying car.

On exhibition at the Boston Automobile Show.

For Low-Powered High-Speed Engines

there is nothing on the market so effective as the new waterproof, high-tension SPLITDORF "E U 4" MAGNETO. In design and construction it is destined to fill a long felt want in the motoring world as low-powered, high-speed machines can now be equipped with a powerful instrument to give their ignition systems the "kick" they have so sadly needed.

Waterproof and dustproof, the "E U 4" SPLITDORF magneto is made throughout on a principle of strict utility combined with natty appearance and reserve power sufficient for a 30 horsepower motor at high speed.

It is a simple instrument, simple in wiring and easily installed to produce the hottest of hot, fat sparks and guaranteed to give the small high-speed engines a flexible ignition system and a world of reliable "pick-up" power never before attained.

SERVICE AND DISTRIBUTION GUARANTEED

The *multiple* point spark plug is superior to the single point plug!

The continual sparking between two points, on cars equipped with a magneto, has a tendency to so widen the gap that finally the spark cannot jump across—and a single point plug fails to spark.

With the multiple point plug, under such conditions, another point immediately takes up the spark—with no loss of power.

This is but one of the reasons why
everyone should use

BETHLEHEM ^{FIVE POINT} SPARK PLUGS

No leakage in compression possible—because of patented gasket construction.

No priming plugs necessary because the long points deliver the spark directly into the gas, starting the car easily and quickly.

Bethlehem plugs have been *proven* to develop more power on less fuel consumption.

Note the placing of the plug in the cylinder head.

Explodes all the gas and produces a hotter spark.

It is economy to buy Bethlehem.

Types for all engines.

Three sizes—metric, ½ inch, ⅞ inch (also made in motorcycle type with both mica and mica-porcelain insulation).

All dealers, \$1.25 each, or by mail on receipt of price.
Booklet Free.

Your Success—And Ours

There is a great similarity between men and motor cars; each possesses characteristics that make them desirable or unfit.

When you set out to find a man to work for you, you don't hire the most flashily dressed man you meet; neither do you hire the fellow who talks the most.

You look rather to what that man has to offer you for the money you plan to lay down for his salary.

If you choose such a man, because of his good appearance and find that under that resplendent appearance there is nothing to back it up: what do you do?

And if you are impressed by his fluent conversation and discover that his entire brain is in

his mouth; chances are ten to one you stop his pay check.

There is a great similarity between men and motor cars.

Many a car has found favor through its paint job; in fact a good finishing department is the salvation of poor construction; for a time.

Many an advertising man has gained a dealer's confidence by his assumed sincerity in the product he was selling.

But as with men, motor cars must deserve such trust in order to hold the ground thus gained.

There is a law in human affairs that rewards the fit against the unfit; that sends the deserving up the success ladder with exactly the same speed as it tumbles the unworthy down.

HOWARD

130" Wheel Base

Your Profits—And Ours

Now the point behind all this is that you, as a motor car dealer, must be very sure of your ground before you enter into a binding contract with anybody.

We want to put before you in very simple terms, the high character of the Lexington-Howard organization; its methods; its value to you.

Then we want you to judge us, our sincerity, our responsibility; solely upon your own knowledge of human nature.

First of all the Lexington-Howard is an organization of specialists; men who have spent their lives in perfecting themselves in their individual lines.

These men have proved their experience in profit paying plants before they entered ours.

We don't want you to take our word for this; we want you to make us prove it.

What you are most concerned with is our method of manufacture and the provision we have made for our permanency in the automobile business.

The Lexington-Howard plant has been most carefully and profitably departmentized.

Each part of the car represents a unit of manufacture; each unit is working every day at a profit.

The fact that we have made so liberal a provision for our dealers is only good business.

Unless you as a dealer receive the proper share of profits you will not remain in business; and it is upon you and you alone that our future as motor car manufacturers must rest.

Then if you will ask us for our sales proposition you will receive another very pleasant surprise; because it's your interest that's at the bottom of this whole affair.

We have laid our plans along lines that mean your success and ours; which, of course, means your profit and ours.

Don't be satisfied with merely reading this announcement. Write today and ask us to tell you just wherein the value of the Lexington-Howard organization lies. We will show you very quickly that there are a great many reasons why you should sell the Lexington "Four" and the Howard "Six" in your city.

HOWARD COMPANY

Connersville, Indiana, U. S. A.

PUBLISHER'S COMMENT.

Since the Boston Automobile Show is the largest of the year, either in this country or abroad, it is particularly fitting that this Annual Advance Boston Show Number of The Automobile Journal should serve the purpose of a reference book of the industry for the 1914 season. This fact has been borne in mind during the preparation of the text matter, but special attention may be drawn to the advertising pages, as supplementing in the fullest degree the presentation of essential facts contained within the body of the magazine. The co-operative efforts of advertiser and publisher have been such as to result in a number which undoubtedly will be highly prized and retained for constant use throughout the coming year.

The Succeeding Issues will be replete with information concerning the greatest of all automobile exhibitions, the Boston Automobile Show, both with respect to the display of passenger vehicles, cyclecars, motorcycles and accessories, March 7-14, and the only commercial vehicle display of national proportions this year, March 17-21. You will need these review numbers. Order

now--direct, or through your news dealer.

Despite the Space devoted in this number to special features of more than ordinary interest, none of the regular departments has been omitted. The section given

over to New Accessories (page 36) appears in each issue, and it is the aim of the publisher to present therein all that is new and of direct, personal interest to the motorist, as designed to make for his comfort and convenience in the use of the car, or economy and efficiency in its maintenance and operation. Two other departments, that containing Suggestions for New Owners (page 33) and that devoted to Correspondence with Reader (page 40) are particularly intended to meet the needs of those who seek practical information upon any problem encountered, and readers of The Automobile Journal are invited to make full use of them.

The Buyers' Guide on pages 85-96, inclusive, is of exceptional value to those who desire to purchase new cars, accessories, supplies and fittings. The concerns listed are wholly reliable and worthy of your consideration in every way.

Why

The Chart shows the results of a series of tests conducted for us at the Worcester Polytechnic Institute to determine the relative superiority of Multibestos over five other leading brake linings.

Just exactly how much superior Multibestos is in various braking qualifications is shown by the chart.

The figures from 0 to 36 represent units of pressure on the brake pedal. Figures from 0 to 100 represent the braking effect on the car wheel.

So, taking 16 units pressure, Multibestos shows a braking effect of 57; the other linings from 48 on down to 26, or from 85% down to 45% of the efficiency of Multibestos.

Insure the safety of the cars you sell by seeing that they are Multibestos equipped.

Review
April 10

Suppose Your Lights Failed Suddenly!

You have been in a theatre or at home when the electric lights went out, because something went wrong at the power house. Next time it happens, stop and think!

Suppose you were travelling in an automobile, at 15 or 20 miles an hour, when the light failed without an instant's warning!

Remember that when a light snaps out and pitches you abruptly into darkness, you are blinded for several moments.

What might happen in just these few moments before you could see where you were steering? Suppose you were driving on a slippery road or toward a turn with a steep ditch before you!

Electric light from a power house, generated and cared for by experts, is fairly reliable.

But electric light on the automobile is apt to fail at any moment, and from dozens of causes, and pitch you into—what?

Prest-O-Lite

cannot fail suddenly. There are no delicate connections or "short circuits." Even should your supply of gas run low, the light dies down slowly, giving ample warning and usually with sufficient time to drive to the nearest town or village where you will find Prest-O-Lite exchange service.

Added to this great safety factor of Prest-O-Lite—you will find its light far more efficient for driving at night. The beams show the road *directly in front of the car* and to either side of the road—not concentrated in a dazzling ray of light on some church steeple a half a mile ahead. There are no tiresome shadows and "rings" of light which tire the eye and confuse the driver.

Prest-O-Lite consumes no engine power, and is operated at one-third to one-fifth the cost of electric light. It breeds no troubles and needs no expert attention.

EXPERIENCE!

"Our car was equipped with what we know to be as good an electric lighting plant as the market affords. Yet we were constantly in trouble. First one light and then the other, or perhaps both would suddenly go out without any apparent cause, and this usually happened when the car was most needed."

"Aside from the inconvenience, the repairs and replacements made it a very expensive lighting system to operate."

"As a solution to troubles, we decided to install Prest-O-Lite and since this has been done we are pleased to say that we now have a light that not only is inexpensive, but is absolutely reliable, and can now enjoy an evening's ride without the constant fear of being suddenly thrown into darkness."

(Name on Request)

You get all the convenience of "push-the-button" operation with the Prest-O-Lite, which lights and extinguishes gas lamps from the dash.

A VISION

**of your car,
dangerously skidding
on the slippery
pavement ahead——**

You have neglected to put on Weed Chains.

You anxiously view the slippery pavement ahead, and have *a mental picture* of your car "side-swiping" a fellow motorist.

Why nurse anxiety and coax calamity — why take such chances when you know

Weed Anti-Skid Chains

Absolutely Prevent Skidding

If you don't equip your car with Weed Chains, and put them on when the roads are slippery and muddy or covered with snow and ice, you are taking chances on your own life and are a serious menace to every road user.

Weed Chains *do not injure tires* even as much as one little slip or skid—They are slipped on in a minute without a jack—*they never fail* in an emergency. Join the *safety campaign*—exercise caution. *Equip your car with Weed Chains today.*

AMERICA'S LARGEST CO-OPERATIVE GARAGE.

Splendidly Appointed Structure Recently Occupied by Massachusetts Automobile Club in Boston---Detailed Description of Various Departments and Methods Employed to Provide for Comfort and Convenience of Membership.

THE Massachusetts Automobile Club, Boston, Mass., occupies a unique position in the industry, from the fact that it was the first organization of this character in America to operate a garage on the co-operative principle. At the time, 1902, there were very few garages of any description in this country, and the industry as such was only just beginning to take on the aspects of a commercial reality. Last month the club took possession of its handsome new clubhouse and garage at Stuart and Clarendon streets, just off St. James avenue—the large-

est and most completely equipped institution of its kind in America, if not in the world.

J. Ransom Bridge, Conrad J. Rueter, L. E. Knott, Eleazer Cate, Wilbert E. Bartlett, John Brisbane Walker, Jr., Ernest L. Rueter and William A. Rolfe organized the Massachusetts Automobile Club Oct. 29, 1900. Jan. 11, 1901, the Automobile Club of New England was formed. These two were consolidated, under the former name, Nov. 4, 1901. Work appears to have been begun almost immediately thereafter on the clubhouse and garage on Boylston

Handsome New Clubhouse and Garage of the Massachusetts Automobile Club, Boston—Largest Building of This Character in the Country.

Recreation Room, at Disposal of Chauffeurs During Their Waiting Periods.

street. The club has been located on Boylston street continuously since that time, until the completion of the building illustrated and described herein.

Description of the Building.

The structure comprises seven stories and basement, and the construction is of brick and concrete throughout. Every precaution has been taken to provide fireproof qualities, and to this end a most up-to-date sprinkler system has been installed, this virtually being two systems in one, since one-half of the building is served by one set of sprinklers and the other half by another. All doors leading into the elevator shafts are arranged to operate automatically in connection with the sprinklers, and by this means it is possible to completely shut off each of the garage floors, for instance, from all other portions of the building. There is no exposed wood work, except in the offices, reception rooms, etc. It is believed that the building is in every way as nearly fireproof as it is possible to make it.

Reception Room, Occupying a Large Portion of the Stuart Street Front, Second Floor, with Directors' Room and Kitchen in the Distance.

Storage space is provided on six floors, and the main portion of the basement is given over to dead storage, so that it is possible to house some 350 cars. Each of these floors is arranged exactly the same, and the system evolved for the movement of cars, on the floors and upon entering and leaving the building, is most interesting and exceedingly practical.

With the exception of first, second and third floors, where there are but three rows of stalls, there is provision for two rows of machines down the centre and one on either side, an open space being reserved between the cars in the

One Corner of the General Offices, Second Floor.

middle of the floor and those at the side. Electric elevators communicate with all floors. There are three of these, one reserved for incoming cars and two for outgoing. The reason for this arrangement is found in the fact that the congestion is most noticeable among machines leaving the building. There are hours, those immediately preceding a large reception or the opera, for example, when this congestion is decidedly marked. At times it becomes necessary to use all three elevators for outgoing cars.

Machines enter the building at the door nearest the Clarendon street corner (that shown at the

right in the accompany illustration), and proceed down the aisle on that side to the incoming elevator at the rear, providing, of course, they are not stationed on the first floor. Upon reaching the proper floor the car is backed off the elevator and run to the left, around the stalls in the centre, until it reaches its own space.

In leaving the building the car proceeds around the open space or aisle, always moving toward the left, backs onto one of the outgoing elevators, in which position it is ready to be driven directly out the front door (that shown at the left) upon reaching the street floor. Thus it will be seen that cars always are moving in one direction and the possibility of confusion

Well Lighted Double Washstands Are Provided on Each of Garage Floors.

Work Bench for Minor Jobs in Centre of Repair Shop.

in this respect is thereby reduced to a minimum.

Each floor is in charge of a man whose duty it is to signal for the elevator, whenever it is desired to take the car out, as well as to superintend the movement of the cars on his floor for washing, etc. Between the elevator wells is a double washstand, equipped with every facility for thoroughly cleansing the cars, this including vacuum cleaners for the upholstery, etc., and compressed air for tire inflation. Except when entering or leaving the building machines are never operated under their own power.

Directly in front of the washstand is a telephone booth, by means of which it is possible to

communicate with the switchboard, etc. In case the chauffeur is not in the building when his employer calls, and it is desired to leave special instructions for him, these are posted on a bulletin board at the side of the telephone booth on the floor on which the car is located.

Recording Entrance and Exit.

On the first floor, along the Clarendon street side, are: First, the superintendent's office and switchboard; then, the stairway leading to the general offices and reception room, etc.; next, the ladies' room, and behind that the stockrooms, and at the extreme rear, the entrance for chauffeurs and employees. H. V. Chamberlain is superintendent and C. A. Edwards his assistant.

The doors for the entrance and egress of cars are operated by individual electric motors. In order to comply with the statutes of Massachusetts with regard to recording the arrival and departure of all cars from a garage, attendants are located in small booths just inside these doors. These men not only take note of the car num-

The Electrical Room Is on the Seventh Floor, Adjoining the Repair Shop, and Is Equipped to Handle All Necessary Battery Work.

The Equipment in the Machine Shop Is Complete in Every Detail—Toolroom at the Rear.

bers in accordance with the legal requirement, these being recorded on daily loose leaf sheets, but advantage is taken of their presence to add another interesting feature in connection with the service rendered to club members.

Keep Track of Chauffeurs.

Each chauffeur is given a number, and, since there is provision for 300 cars on regular storage, exclusive of those on dead storage, a board is placed over the telephone switchboard, which carries 300 numbers. Whenever a car approaches the entrance, it is reflected in a mirror hanging in the proper position, and the operator at the door depresses a lever which connects the electric motor with a set of spring releases in such manner as to cause the door to slide open. As the car enters the building the registration number is noted and checked on the daily sheet. At the same time a button is pressed, which causes a black disc over the chauffeur's number on the board above mentioned to expose the number,

signifying that that chauffeur is in the building. A similar plan is followed with reference to cars leaving the building, with the exception that the black disc falls into place over the chauffeur's number, indicating that he is not in the building. In case the chauffeur does not go out with the car, but uses the rear entrance, another operator at that point transmits this information by pressing buttons at that door. The advantage of the system lies in the fact that the telephone operator is able at all times to inform the employer whether or not the chauffeur is in the building.

In the stockrooms are to be found such accessories and supplies as are likely to be needed. These are in charge of the superintendent or his assistant and cannot be secured without his knowledge. The rooms given over to lubricants and gasoline are provided with every facility for readily handling these supplies. In the basement, runways and adjustable tracks make it an easy matter to roll a barrel of oil or gasoline into place, and from these self-measuring pumps extend into the rooms above.

Handsome Reception Room.

The entire Stuart street front of the second floor is given over to the reception room, directors' room and kitchen. These are handsomely appointed and contain every convenience for serving lunches, etc. It is purposed to add a library and other comforts for entertaining visitors from other cities. This is part of a plan now under consideration, by which special cour-

General View of One of the Garage Floors, All of Which Are Arranged Practically Alike, with Open Space Be-

tesies will be exchanged between members of this club and the Automobile Club of America in New York City and the Automobile Club of Philadelphia. Along the Clarendon street side are the general offices of the club, in which are the filing cabinets for members' accounts, etc. All these rooms are finished in mahogany and the furniture and decorations are strictly in keeping with the uses for which they are intended.

On the third floor, above the general offices, is the chauffeurs' room. This is really two rooms in one. The entrance is from the rear of the building, and directly into the main waiting room, which is equipped with billiard and pool tables, and provisions for other games. Separated by a glass partition is the reading room, where all the latest technical, trade and current literature is available.

The Repair Shop Floor.

The top floor is given over entirely to the repair shop, and a factor of decided prominence is the abundance of light available. The elevators also communicate with this floor. Between the wells, in the space occupied on the other floors by the washstands, chauffeurs are permitted to work on their own cars. In front of this space is the entrance to the office, in charge of V. J. Oglivie as foreman and J. Brandy as assistant.

Along the north side—the Stuart street front—is the work bench, an arrangement which not only affords a maximum of light, but one which is designed to take advantage of the light from

Looking Down the Aisle Between the Work Bench and Trolley Hoists in the Repair Shop.

the north, which is considered the most constant. Directly behind this is a double trolley hoist, by means of which it is possible to pick up either end, or both, of the chassis at will, take out a motor, etc., without disturbing the relative position of the chassis. Every necessary tool is provided. This applies as well to the work bench for smaller repairs through the centre of the room, directly under an ample skylight.

Machine Shop Equipment.

The machine shop is set off from the main portion of the room, on the Clarendon street side, by a wire netting partition, and the equipment of this department includes a number of machine tools which are not usually to be found outside the automobile factories. Mr. Oglivie maintains that he is able to undertake any piece of work which is likely to be presented. This is a desirable factor, since many of the cars stored in the

Between the Rows of Stalls, in Which Cars Are Required Always to Move in the Same Direction to Avoid Confusion.

garage are of foreign manufacture, for which spare parts may not be secured readily.

Back of this is the tool room, presided over by one of the men in the machine shop. Each workman is supplied with 10 brass checks, bearing an individual number. Whenever he desires a special tool he exchanges one of these checks therefor, and as soon as it is returned he receives his check in exchange. In this manner it is possible at all times to account for the entire tool equipment.

Chauffeurs May Work on Cars.

It may be added that chauffeurs who desire to work on their own cars in the space provided for that purpose, may also acquire the use of these tools. A given number of checks, similar to those used by the employees of the club, but slightly different in shape, are sold for a stated price, the service thus contracted for to be taken advantage of within a certain time. These checks are exchanged for tools in exactly the same manner as has been described with reference to the workmen.

On the other side of the building, beginning at the front, are the blacksmith shop, the storage space for tires and inner tubes, and the electric charging room, in the order named. The electrical equipment is complete in every particular for charging, repairing batteries, etc., and is in charge of a competent battery expert.

Nothing has been left undone in an effort to provide every comfort and convenience for the club member and his chauffeur. In addition, the club seeks to afford all necessary service, so far as this may be at all practicable, on a co-operative basis, and as nearly as possible at cost. It is maintained that in no sense is the institution a money making venture.

Property Held by Trust.

The property is now held by the Massachusetts Automobile Club Trust, a realty trust organized for this purpose. During the life of the club in its location on Boylston street, a considerable fund was accumulated from initiation fees, annual dues, etc., and this was materially increased, of course, by the sale of that property. It was, however, necessary to secure additional money for the erection of the present building.

As devised, the plan was as follows: Each resident member was presented with five shares in the Massachusetts Automobile Club Trust, and each non-resident member 2.5 shares, in exchange for their interest in the fund above mentioned, and in the sale of the Boylston street property. Each resident member also was permitted to purchase five shares, and each non-res-

ident, 2.5. Additional money was raised by mortgage.

Some stock of the realty trust is still retained in the treasury, and will be issued, one share, par value \$50, to each new member. The trust will continue to hold the property, the Massachusetts Automobile Club paying rental therefor by turning over to the trust all initiation fees and annual dues. For a time, of course, these payments will serve to meet the interest on the mortgage and to reduce the principal. In time, it is anticipated there will be opportunity to declare dividends, but even then, it will be seen that the co-operative feature should be reserved, since the members of the club hold the stock in the trust, and it is provided that whenever such stock is for sale it shall first be offered to the directors of the club.

Policy of the Club.

In the early days of the industry, the Massachusetts Automobile Club promoted a number of events calculated to encourage experimentation and development. Thus, for instance, before the formation of the Boston Automobile Dealers' Association, the Boston automobile show of 1902 was held under the club's auspices. In recent years, however, the entire activities of the organization have been directed wholly toward providing for the needs of its members along the lines indicated herein, and this policy will be continued in the new building.

The present officers of the club are: President, William H. Ames; first vice president, Bancroft C. Davis; second vice president, William A. Rolfe; treasurer, Frank W. Remick, and secretary, Arthur Brooks.

ELEVEN ENTRIES NOW.

Numbers Are Drawn by Cars Listed for the 500-Mile Race at Indianapolis.

The management of the Indianapolis motor speedway, on which the fourth 500-mile race for the International Sweepstakes trophy will be held Memorial Day, announces that 11 cars have been entered for this event. This does not include the two Maxwell cars, which are being constructed under the direction of Ray Harroun, who won the first 500-mile race in a Marmon.

Numbers have been assigned to the 11 above mentioned as follows: Burman, Burman, 1; Cooper, Stutz, 2; Anderson, Stutz, 3; Wilcox, Gray Fox, 4; Keene, Bullet, 5; Goux, Peugeot, 6; Boillot, Peugeot, 7; Chassagne, Sunbeam, 9; Guyot, Delage, 10; Christiaens, Excelsior, 12; ———, Burman, 17.

ENGINE MAKERS' MEETING.**New Association Discusses Conditions Affecting Business of Members.**

The organization of the Automobile Engine Manufacturers' Association was noted in these columns recently. At the last meeting it was announced that about 60 per cent. of the makers in the industry was represented in the membership and that the output of these manufacturers was about 85 per cent. of the total.

One of the questions discussed at some length was the lack of results obtained from motor shows, and practically all present agreed that the returns did not warrant the time and expense incurred in making display. A canvass among all motor manufacturers was inaugurated to determine whether or not such exhibition should be eliminated hereafter.

It also was decided to make all contracts as strong and binding as possible. The matter of losses through deferring of contract shipments was discussed, and it was purposed to regulate this condition by adopting charges which would prove remunerative. Credits will be gone into thoroughly, and it was purposed to prosecute all defalcations, and attempts at imposition will be safeguarded by making them public, so far as possible.

The next meeting will be held in Chicago, March 20. The office of the new organization has been established at 603-608 Monadnock building, Chicago, with M. Wulpi in charge as commissioner.

SECOND PITTSBURG DISPLAY.**Fourth Annual Exhibition of the Pittsburgh Auto Show Association Most Successful.**

The fourth annual exhibition of the Pittsburgh Auto Show Association, under the management of J. H. Zimmerman, was held in Exposition hall, Pittsburgh, Penn., Feb. 14-21, this being the second display of automobiles and accessories for that city this year. The event was a decided success, new records in number of exhibits, attendance and sales being established.

The main floor of the hall, which is the largest single room in the city, free from pillars or

obstructions of any nature, was completely filled with cars and trucks. Particular attention was directed to the latter, because of the exceptional interest which has been manifested in this type of vehicle in Pittsburg during the past few months. The cyclecar also was a decided attraction and many sales were recorded during the week.

SALES POLICY CONVENTION.**Splitdorf and Apple Executive and Branch House Heads Gather in Dayton.**

With the recent reorganization of the Apple Electric Company of Dayton, O., through the financial and active support of the Splitdorf Electrical Company, Newark, N. J., the selling and distributing of the products of the Dayton con-

Representatives of Apple Electric and Splitdorf Electrical Companies in Convention at Dayton, O.

cern will, in the future, be conducted through the branch houses of the Splitdorf company. At a recent sales policy meeting of the executive and branch heads of both concerns, held in Dayton, plans in connection with this arrangement were discussed fully. The following were present:

F. A. Cornell, business manager; C. P. Brockway, sales engineer; R. S. Allen, European representative; H. E. Berger, engineering department; C. F. Succop, sales department; R. H. Croninger, factory manager; V. A. Apple, president, and H. F. Apple, sales department of the Apple Electric Company.

H. J. Hinley, manager of branches in Detroit, Dayton and Cincinnati; E. A. Kelley, manager of Chicago, Kansas City, Dallas and Minneapolis branches; R. S. Preble, president of Boston and Chicago branches; O. J. Rohde, treasurer and manager of New York City, Newark, Philadelphia, Atlanta and Toronto branches; F. A. Storer, president, Buenos Aires branch; E. A. Bracket, engineering department; D. R. Walls, advertising manager; C. W. Curtiss, general manager, and W. J. Murray, assistant general manager, represented the Splitdorf Electrical Company.

INCORPORATE MOTOKART COMPANY.**Tarrytown Motor Car Company Finds a Way to Avoid Provision of New York Law.**

Some time ago, when the maker of the Motokart, a four-wheel parcel delivery wagon, sought to incorporate under the laws of New York, it found it could not use the word Motokart. Accordingly, the concern was incorporated as the Tarrytown Motor Car Company. The factory is located in Tarrytown, N. Y., and the general offices in New York City.

It is now announced that papers have been filed in Trenton, N. J., covering the incorporation of the Motokart Company, which is destined to take over the Tarrytown Motor Car Company and the Steinbock Engineering Company. The last named concern has been furnishing the engines and other mechanical units for the Moto-

The event was held in the Auditorium, under the auspices of the motor car dealers' division of the Memphis Business Men's Club. Twenty dealers in cars and an equal number of accessory concerns were represented.

RAYFIELD CARBURETOR CONVENTION.**Salesmen and Dealers Discuss Methods and Policies at Chicago Factory.**

Recently, the Findeisen & Kropf Manufacturing Company called a three-day convention of salesmen and dealers handling Rayfield carburetors, made by this concern, at its factory in Chicago. The event was concluded with a banquet at the New Southern hotel, an accompanying illustration presenting the company seated at the table.

The first day of the convention was given over to the constructive elements of the carburetor industry, and a comparison of the Rayfield with other makes. The men were addressed by Walter Findeisen. The second day, those present took up the question of sales methods and advertising plans. Considerable attention was given to promotion, the discussion being opened by E. A. Bates. The third day was given over to the question of distribution, during the consideration of which it was brought out that the Rayfield carburetor

Banquet of Rayfield Salesmen and Dealers in New Southern Hotel, Chicago.

kart. The new company will be capitalized for \$500,000, and plans are under way for a greatly increased production.

MANY SALES AT MEMPHIS.**Southern City Adds Its Evidence as to General Outlook for 1914 Business.**

Soon after the doors were opened on the fourth annual show of the dealers in Memphis, Tenn., Feb. 16, a six-cylinder Packard car was sold, and this sale was followed almost immediately by the purchase of a Baker electric. Thereafter, business was brisk throughout the week. The attendance was larger than ever before, and the results of the show were such as to completely refute any suggestion that business is not to be good in that portion of the South during 1914.

is sold in practically every city and town in the United States.

The principal address at the banquet was given by H. P. Williams of the advertising firm of Williams & Cunyngnam, who spoke on the subject of "Sales Service".

GLIDDEN TROPHY AWARD.**Somewhat Original and Novel Suggestion as to Disposal of Classic Prizes.**

Although Frank X. Mudd, Chicago, chairman of the touring information board of the American Automobile Association, is said to have under consideration a rather elaborate plan for the disposition of the A. A. A., Glidden and Anderson touring trophies in 1915, when it is proposed to hold a transcontinental tour to the Panama-Pacific exposition in San Francisco,

those in charge of such arrangements for 1914 appear to be very much at sea. It is somewhat well known that the association expects to hold its summer meeting in New England, a special committee, with former President Lewis R. Speare as chairman, having been appointed to have charge of the details.

The Maine Automobile Association has extended an invitation to the national body to unite with it in holding a field day celebration. Similar plans are said to be under way in Massachusetts and Vermont. And in connection with these, it has been suggested that the trophies above mentioned be awarded to those who come to the meeting from the greatest distance in their cars. In order to make this plan possible, with reference to the Glidden trophy, permission will have to be secured from the donor, Charles J. Glidden, to amend the deed of gift, since the trophy was presented to the association as a prize to be awarded in the annual competitive tour.

PLANS FOR FOREIGN TOUR.

Members of Society of Automobile Engineers Will Sail from New York Oct. 10.

The Society of Automobile Engineers has settled upon Oct. 10 as a tentative sailing date for the second European tour. The party will leave New York for Paris, where it is planned to spend at least four days, visiting the plants where Panhard, Renault, De Dion-Bouton, Clement, Peugeot, Delaunay-Belleville and Lemoine cars are produced. Leaving Paris the members will go to Italy, where three days will be spent in Turin and Milan, visiting the Fiat, Isotta, Itala, Lancia, Züst and Bianchi factories.

Lucerne, Switzerland, will be the next stop, with 36 hours of sight-seeing, before proceeding to Schaffhausen to inspect some of the best known electric steel foundries in Europe. Two days will be spent at Stuttgart, Germany, visiting the Mercedes, Daimler, Bosch and Eisemann plants. Then will follow a visit to the Krupp steel works and a trip down the Rhine. In Belgium the Metallurgique and Minerva factories will be inspected.

Although a greater portion of the time during the first foreign tour was spent in England, it is planned to visit that country again, as guests of the Institute of Automobile Engineers, members of which were in America last year. The return will be from Liverpool, arriving in New York about Nov. 18.

MANY AUTOMOBILE BILLS.

Legislatures of Nine States Will Consider a Total of 114 Proposed Laws.

There are nine state legislatures in session at the present time. Six convened during the second week in January and three the third week. In the succeeding five weeks, no less than 30 senate bills and 84 house bills were introduced relating directly to, or affecting directly or indirectly, the use of motor vehicles. These statements are made on the authority of the National Automobile Chamber of Commerce.

Classified by subjects, some of these bills are, in order of their numbers, as follows:

	Senate	House
Fixing registration fees	10	18
Regulating speed and operation.....	4	24
Regulating equipment		11
Lights on all vehicles.....	2	5
Creating highway commissions.....	1	3
Requiring road signs.....		3
State aid for roads.....	1	2
Limiting truck weight and speed.....		2
Licensing all drivers.....		2
Limiting driving age.....	1	1
Requiring wide tires.....	1	1

The nine states and the total number of motor vehicle and road bills introduced in each up to the middle of February are: Massachusetts 44, New Jersey 16, Kentucky 13, Virginia 12, New York 10, South Carolina seven, Maryland six, Rhode Island three and Mississippi three.

Some of the bills are unusually interesting. One requires the payment of \$50 a week for operation of a temporary garage. Another would have all motor vehicles equipped with a device that will scatter 72 metal markers in the street upon striking any object with the front of the car, each marker having stamped upon it the registration number of the machine. The Kentucky senate is asked to prohibit owners of automobiles, doctors and dentists from taking out personal liability insurance. The Virginia house has two bills authorizing Accomac and Spottsylvania counties to levy special licenses on automobiles, in addition to a state registration fee, for the construction of roads in these counties. A Massachusetts bill would make automobile owners fit their cars with headlights or side lights, showing a red light on one side and a green light on the other.

Because of the recent decision of the supreme court in Mississippi that the registration bill enacted in that state was unconstitutional, the legislators have before them a joint bill providing for refunding automobile license fees that were collected before the decision was returned.

BAY STATE AUTOMOBILE ASSOCIATION.

CONDITIONS within the automobile industry have undergone decided change with its increased growth and importance, and methods

L. R. Speare, First President, Bay State Automobile Association.

which at one time were considered efficient have been supplanted by more practical endeavors on the part of those engaged in the manufacture and sale of vehicles and accessories. In the early days, men who had faith in the future possibilities of the horseless carriage were given to forming associations which

had for their main object the encouragement of those engaged in experimental work. This resulted in co-operation between the would-be motorist and those who were to produce that which was to make motoring possible.

That co-operation of this character was desirable cannot be refuted, but it may be contended that with the rapid growth of the business during the past few years, this need for co-operation has been somewhat reversed, and that appears to be the view of the situation which has made its appeal to the Bay State Automobile Association, with headquarters in Boston. This organization has recently inaugurated a new policy, consideration of which undoubtedly will prove of interest.

The Bay State Automobile Association was organized Dec. 1, 1904, its membership being composed very largely of dealers in cars and accessories in Boston. Its first president was Lewis R. Speare, some time later president of the American Automobile Association, with which this body has practically always been affiliated. The reason for its existence was found in the fact that

these dealers felt the need of some such organization to promote automobile contests and other events which would direct special attention to the practicability of the product of what was at that time virtually a new industry.

It would appear, also, that the dealers were interested in the social side of the organization, for, at the first meeting of record, headquarters were established at the Hotel Lenox for six months. The other business of the meeting had to do with the proposition to hold race meets during the summer of 1905, and arranging for a tour to the White mountains.

Association's Early Activities.

Previous to that time race meets had been conducted in the vicinity of Boston by the Country Club of Brookline, June 15, 1901, and the Massachusetts Automobile Club, Readville, June 11, 1904. Two meets were conducted at Readville by this new organization in 1905, one being held Memorial Day and the other, Sept. 9. These appear to have been entirely successful, as the matter of purchasing the Woodlawn Park hotel, in Auburndale, was seriously considered for a time late in 1905.

In 1906 a building on Dartmouth street was leased, and the association became an important factor in the social life of its members. Later, the headquarters were removed to the Hotel Carleton on Boylston street, but eventually the association returned to the Hotel Lenox, where the headquarters have been established for the past several years. Mr. Speare was succeeded as president in 1910 by E. A. Gilmore, who held the of-

Rose Dining Room, Hotel Lenox, Boston, Headquarters of the Bay State Automobile Association.

fice until the beginning of the present year.

Many of the contests conducted by this association were of decided importance to the industry, both as a means of calling attention to motor vehicles in a general way, and as an aid in the perfection of the product. Specific reference may be made to the 100,000 mile non-stop run of 1909. A Maxwell car was the only entrant, and its successful completion of the test established a record which remained unchallenged for a number of years.

New Policy Inaugurated.

But the Bay State Automobile Association feels that the need for this character of activity has passed in a large measure. The practicability of the motor vehicle is now firmly established, and cars may be sold on a strictly merchandise basis.

However, there are other factors to be considered. Dealers and manufacturers are beginning to appreciate that they owe a debt of gratitude for the co-operation extended by the would-be motorists of the early days, and to the owners and users of automobiles since that time.

The Bay State Automobile

Association has decided that the work in mind at the time of organization has been accomplished, and that the time has arrived when it can serve a larger usefulness by co-operating with motorists to the fullest possible degree.

At the recent annual meeting of the association, an entirely new policy was adopted, which is best exemplified by the new motto: "This association stands for fair laws, proper use of the roads and promotion of good fellowship among motorists". These desirable results are considered of importance in the order named.

Boston dealers agree with those of other cities in the opinion that at times owners of cars fail to realize the fullest measure of satisfaction from their use because of the serious handicaps which have been imposed by legislative enact-

ment, and that there is danger of additional restrictions, unless those connected with the industry take steps to protect their interests. A legislative committee will be appointed to have this matter directly in charge.

The proper use of the roads means a careful consideration of the rights of others. The great majority of motorists have suffered quite as much from the lack of consideration on the part of reckless drivers as other users of the highway. It is realized that measures must be adopted to curtail this danger, but it is contended that in many instances those who have sought to be careful have suffered in the unwise administration of existing laws. This association will undertake to employ counsel in an effort to see that automobile owners and users are fully protected in their rights under these laws.

In order to promote good fellowship among motorists, and to place itself in a better position to accomplish the other classes of service contemplated, the Bay State Automobile Association invites owners and dealers throughout the state to become members. Headquarters will remain in the Hotel Lenox, where the use of three rooms is reserved to members, both resi-

J. J. McNamara, Vice President.

**W. H. Stevens, Present President,
Bay State Automobile Association.**

Fred K. Swett, Secretary-Treasurer.

dent and non-resident. One of these is devoted largely to the executive work of the association; the second, to social recreation, and the third, is the handsome Rose dining room, where members and their friends are invited to make themselves at home during business hours, and where the monthly entertainments and annual banquets will be held.

Since the annual meeting the membership has been increased very materially, this being composed of both owners and dealers in Boston and from a number of other cities throughout the

state. The plans are not wholly completed as yet, but with dealers and motorists co-operating to the fullest extent with respect to the matters outlined, it is certain that the industry cannot help but be benefited in every way. Other activities will be inaugurated as rapidly as their need appears to exist.

The officers of the Bay State Automobile Association for the ensuing year are as follows: President, W. H. Stevens; vice president, J. J. McNamara; secretary and treasurer, Fred K. Swett; directors, E. A. Gilmore, R. R. Ross, Dr. H. R. Boyd, Chase Langmaid, Joseph Donovan.

MERCER WINS THE FIFTH GRAND PRIZE.

FORTY miles ahead of the nearest competitor, Edwin Pullen drove his Mercer car, made by the Mercer Automobile Company, Trenton, N. J., across the finish line a winner in the fifth race for the Grand Prize at Santa Monica, Cal., Feb. 28, and for the first time in the history of the event, the award went to an American car. Not only that, but Pullen and his Mercer secured a new record for the event, covering the 403.248 miles in 5:13:00, or at an average speed of 77.29 miles an hour. The previous record was held at 74.07, by the late David L. Bruce-Brown in a Fiat, made during the third race for the Grand Prize at Savannah, Ga., in 1911.

Two days before Pullen and this Mercer took part in the ninth race for the Vanderbilt Cup, and during the 14th lap his machine left the course, while going at an estimated speed of 85 miles an hour, crashing into an iron barricade. At first it was thought that the car was so badly damaged that Pullen would be unable to compete in the longer event. The splendid result is all the more noteworthy in consequence.

Guy Ball, driving a Marmon, finished in second place, his time being 5:53:23. B. Taylor, in a second hand Alco, for which he is said to have paid \$250, was third, in 6:08:29. Ralph De Palma, twice a winner of the Vanderbilt Cup, was fourth, his time being 6:09:08.

Seventeen cars started, and only four finished. Pullen drove an even race from the start, and refused to be led into the many brushes between those who were seeking new speed records. Wishart in a Mercer held the lead until the 23rd lap, when he gave way to De Palma. At this point Wishart risked his life, and probably his chance of winning the race, by swerving off the course to avoid running down an old soldier, who ran in front of the racing cars.

De Palma was forced to stop in the 30th lap, and J. B. Marquis in a Sunbeam took the lead. Gilbert Anderson in a Stutz was second. Less than two minutes later Marquis attempted to take a turn too abruptly, and his machine was overturned. For a time it appeared that the driver was fatally hurt, but later the surgeons announced that his recovery was certain. This was the first serious accident that has occurred on the Santa Monica course, admittedly the fastest in the world.

On the 35th lap Pullen went into the lead. De Palma lost considerable time at the pits at this point, and at one time it was announced that he had withdrawn from the race. Suddenly, with Pullen only eight laps to go, De Palma re-entered the contest. Anderson withdrew at this point, and thereafter there was no doubt as to the result, insofar as the winner was concerned.

As was true of the Vanderbilt Cup race, two days previous, Bosch ignition and the Boyce Motometer made clean sweeps, being fitted to all cars taking part in the event. Pullen's Mercer was fitted with Palmer-Cord tires. Braender tires also figured in the results, De Palma's Mercedes being thus equipped.

Pullen's prize money was \$3000, plus a Bosch award of \$500; Ball secured \$2000 and a Bosch prize of \$150; Taylor, \$1500 and \$100 from the Bosch Magneto Company, and De Palma added \$1000 to the amount won in the Vanderbilt Cup race, as set forth on the next page.

W. S. Campbell has been appointed advertising manager of the Miller Rubber Company, Akron, O., maker of Miller tires. He has had several years' experience in the advertising field, and was for a time circulation manager of the Iron Trade Review and Daily Iron Trade.

HISTORY REPEATED IN VANDERBILT RACE.

DRIVING the same Mercedes car with which he won the eighth race for the Vanderbilt cup, at Milwaukee, Oct. 2, 1912, Ralph De Palma crossed the finish line in the ninth contest for this award at Santa Monica, Cal., Feb. 26, without once stopping during the 294.035 miles, his time for the distance being 3:53:41. Not only did De Palma thus take the trophy twice in succession, thereby duplicating the performance of Harry F. Grant in an Alco car, but he created a new record for the classic, 75.51 miles an hour, as against 74.07, made by Ralph Mulford in a Lozier in the seventh race at Savannah, Ga., in 1911. The record for the course, 78.5, a world's record made by Teddy Tetzlaff in a Fiat, in the Santa Monica road race of May, 1912, was not endangered.

The history of the eighth race was again repeated, when Barney Oldfield crossed the line a little over a minute behind De Palma. His mount was a Mercer, and Hugh Hughes in a Mercer took second place in the race of 1912. Oldfield's time was 3:55:01, and his speed 75.07 miles an hour. He was forced to stop once, on the 34th lap, to change a wheel.

For Spencer E. Wishart in a Mercedes, third place combination in the Milwaukee event, substitute William Carlson, Jr., in the Mason used by Ralph Mulford to create a world's record for 200 miles on a dirt track at Columbus, O., July 4, 1913. The Stutz took fourth place in both events, in 1912 with Gilbert Anderson at the wheel, and at Santa Monica, with Earl Cooper, the hero of the 1913 racing season. George Joerman in a Touraine was fourth this year.

Sixteen cars were entered for the event, and 15 started. Only five finished. Grant in an Isotta, and Lewis in a Mason failed to make the first round. Wishart in a Mercer finished this lap in the lead, closely followed by Anderson in a Stutz and Pullen in a second Mercer. Wishart went out on the third lap. Anderson took the lead in the 14th and held it until the 18th, when he went out. Thereafter it became a race between De Palma and Oldfield for first position.

Besides winning the trophy, De Palma took \$3000 in prize money, Oldfield \$2000, Carlson \$1500 and Cooper \$1000. The Bosch Magneto Company also offered special prizes for place cars fitted with Bosch ignition, and, inasmuch as A. H. Bartsch of that company recently telegraphed East that all cars entered were Bosch equipped, it seems safe to add \$300, \$150 and \$100 to the amounts won by the first, second and third men, respectively.

Braender tires, made by the Braender Rubber & Tire Company, Rutherford, N. J., also figured prominently in the result, since it is conceded that De Palma owed his victory very largely to the fact that he was not obliged to stop once throughout the race. Braender tires were fitted to De Palma's Mercedes, Oldfield's Mercer, Carlson's Mason and Cooper's Stutz.

It will not prove amiss at this time to state that Braender tires first came into prominence in racing circles during the 500-mile event on the Indianapolis speedway last Memorial Day, when Ralph Mulford drove his Mercedes the entire distance without tire change. Later in the season Braender tires assisted Mulford and a Mason car in creating the new world's dirt track record for 200 miles at Columbus, O., without a tire change.

Mercedes Car with Which Ralph De Palma Won Eighth and Ninth Vanderbilt Cup Races.

This same car and the same set of tires went through the two days of racing at Elgin, Ill., in August, finishing in second place the second day, and still later competed in five-mile races on the Galveston beach course, until it is estimated that they went at least 900 miles in contests before being discarded.

Another accessory which occupied a prominent place at the finish was the Boyce Motometer, made by the Motometer Company, 1790 Broadway, New York City. This little device, which is fitted in the filler cap of the radiator and registers the temperature of the cooling fluid, was fitted to all the cars which finished in the Vanderbilt Cup race. Indeed, it is stated by Secretary H. H. Boyce of the Motometer Company, that every car competing in the two Santa Monica events was equipped with this device, which is intended to forestall overheating of the motor.

TWELFTH ANNUAL BOSTON DEALERS' SHOW.

Detailed Plans for the Biggest Exhibition of Automobiles in the World—Only Motor Truck Display of National Prominence This Year—List of Exhibitors.

BOSTON might fittingly be described as the cradle of the automobile industry in America. Long before the commercial possibilities of the horseless carriage were recognized generally, business men in that city apparently were able to foresee, at least in some measure, that one day the manufacture and sale of motor vehicles was to become an industry of sufficient magnitude to

warrant encouragement of those who were engaged in early experimentation. Although the forthcoming Boston automobile show, March 7-14, for pleasure cars, and March 17-21, for commercial vehicles, is styled the 12th annual display, it really is the 16th to be held in that city.

Chester I. Campbell, General Manager, Boston Automobile Show.

The first showing of horseless carriages in America was made in connection with the Mechanics' fair in Boston in the fall of 1896. There were three vehicles, one propelled by steam, a second by gasoline and the third, Kenneth Skinner's imported gasoline tricycle. They formed a part of the bicycle exhibit in the basement of Mechanics' building, in which structure the 1914 display will be held, and where practically all of the Boston shows have been staged. Two years later, for the Mechanics' fair was held only every alternate year, the second automobile show in America took place under the same auspices, and the number on display was increased to five or six.

The third Boston show was held in 1901, in connection with the formal opening of a sales agency for Knox cars on Stanhope street by the firm of Reed & Underhill, composed of George Reed and A. P. Underhill. The fourth was in

1902, under the direction of the Massachusetts Automobile Club in Grand hall, Mechanics' building, and was a most pretentious presentation of the industry's product. In 1903, the dealers of Boston took charge of the enterprise, under the personal management of Chester I. Campbell, and the exhibition of that year has come to be known as the first annual dealers' Boston automobile show.

Boston Dealers' Shows.

The following year, 1904, the Boston Automobile Dealers' Association was formed, and this body had complete charge of the Boston shows until 1912, when it was deemed advisable to separate the business vehicles in a display to be held the week following that for pleasure cars, and the Boston Commercial Motor Vehicle Association was formed to have charge of this section of the exhibition. Chester I. Campbell was retained as manager of both associations, and he has had personal direction of all dealers' shows, as well as numerous motor boat and aeroplane displays in the same building. The statistics of the several Boston automobile shows, so far as they are available, are presented in an accompanying table.

The decrease in number of cars on display in 1908, over that for 1907, is explained by the fact that several concerns were forced to go out of business or to form consolidations during the financial depression of that period. But it will be noted that there has been a steady gain in attendance from the beginning, and in the amount of business transacted the Boston show always has established a new record each year. At the conclusion of the display in 1913 the dealers reported sales aggregating more than \$2,000,000.

GROWTH OF THE BOSTON SHOW.

Year	Makes on Display—		Totals	Attendance
	Pleasure	Commercial		
1903.....	21	*	21	17,360
1904.....	30,000
1905.....	47,000
1906.....	52,165
1907.....	115	6	121	57,213
1908.....	77	7	84	69,000
1909.....	88	18	106	92,000
1910.....	97	25	122	107,600
1911.....	102	41	143	146,363
1912.....	107	66	173	225,000
1913.....	108	68	176	245,000

*Commercial vehicles not listed separately.

The Boston show first secured an international record in the number of cars on display in 1910, when there were 122 different makes and a total of 650 complete cars and chassis on view. The previous record was the Olympia show in London for 1909, when 597 cars and chassis were exhibited. Boston still holds this record, the nearest approach to either mark being the Olympia display of 1910, when 590 cars and chassis were shown.

By way of making comparison with other shows held this season, it may be stated that there were 132 makes represented at the Automobile Salon in Paris, 126 at the Olympia show in London, 79 at the Grand Central Palace in New York and 86 at the Coliseum show in Chicago. The foreign shows do not make the distinction between commercial and pleasure vehicles that is made in this country, and it is only fair in this connection to consider the total number of makes listed for the two sections of the Boston show in making comparison. There are at present 88 makes of pleasure cars and 50 of trucks and business wagons, making a total of 138, which exceeds that of any other show held this season, but, inasmuch as it always has been true that many makes are entered at the last moment, it is safe to predict that this total will be increased very materially before the doors actually open on the second section of the 1914 display. March 17, and Boston is assured of securing another international record in this respect.

Only Truck Display.

This year's Boston show occupies a unique position, because of the fact that it will present the only exhibition of motor trucks and business wagons of national proportions to be held in America this year. As has been stated, the Boston show always has been a dealers' proposition, but its size, in every respect, has at all times been such as to make it rank above even the national shows in New York and Chicago.

As in previous years, the show will be held in Mechanics' building on Huntington avenue. And for the first time in the history of this "Greatest Automobile Show on Earth", the tower will be resplendent with illumination, attracting the attention of the public even from Copley square. In

addition, the exterior of the building will be brilliantly illuminated in a manner distinctively new and attractive.

While no definite announcement has been made concerning the decorative treatment of the interior, it is known that the general motif will be Italian in character, nearly all of the details being from drawings made by Architect Ernest W. Campbell, brother of the manager, while on a special tour through Italy last summer.

The main entrance will be through Exhibition hall, which will be approached through a corridor of marbleized panels, with statues standing out in bold relief against a dense background of foliage, and a magnificent Roman arch. All the massive beam work in Exhibition hall will be completely concealed by handsomely painted en-

Mechanics' Building, Scene of 12th Annual Boston Dealers' Automobile Show.

tablatures, in the Roman style of architecture, while massive columns of verde antique bronze, surmounted by large illuminated glass globes, will set off the various exhibition spaces.

But it is in Grand hall that the architect always has developed his best decorative work, and this year the setting will be Venetian. It is impossible to state the manner in which this will be worked out, beyond citing the fact that the curtain at the rear of the stage will present a cyclorama of the City of the Doges, resplendent in colors, 90 feet long and 30 feet high. The entire ceiling is to be covered with a massive canopy effect, pierced to present open carved work, from which will be dependent eight electroliers, each composed of 12 Venetian wrought iron lanterns. The arches surrounding the entire hall are to be studies adapted from the Ducal palace.

VEHICLE EXHIBITORS AT BOSTON SHOW.

(Where No City Is Given, Address Is That of Boston Agent, Distributor or Branch.)

GASOLINE PLEASURE CARS.

100, 100aa Abbott-Detroit—F. A. Dutton Motor Co., 76 Huntington Ave.
 311 Allen—Allen Motor Co., Eostoria, O.
 232 Apperson—Varnerin & Paddon, 1926 Columbus Ave.
 116 Briscoe—V. A. Charles, 616 Commonwealth Ave.
 136-140 Buick—Buick Motor Co., 17 Lawton St.
 2 Cadillac—Cadillac Automobile Co. of Boston, 372 Boylston St.
 421 Car-Nation—W. B. Doan & Co., 1112 Boylston St.
 326, 327 Cartecar—Hollander Motor Co., 1070 Boylston St.
 101 Case—J. I. Case Threshing Machine Co., 8 Columbus Ave.
 108, 109 Chalmers—Whitten-Gilmore Co., 620 Commonwealth Ave.
 35 Chandler—R. B. Nettleton, 1118 Boylston St.
 107 Chevrolet—Chevrolet Motor Car Co. of N. E., Motor Mart.
 36, 37 Cole—Cole Motor Co. of Boston, 94 Massachusetts Ave.
 113, 114 Flat—Flat Motor Sales Co., 839 Boylston St.
 117, 118 Ford—Ford Motor Co., 650 Beacon St.

 422-424 Velle—Frank L. Roberts, 320 Newbury St.
 147, 148 Westcott—Westcott Motor Car Co. of Boston, 341 Newbury St.
 7, 11 White—White Co., 930 Commonwealth Ave.
 226, 237 Willys-Knight—R & L Co., 915 Boylston St.
 6, 10—Winton—Winton Motor Car Co., 674 Commonwealth Ave.

ELECTRIC PLEASURE CARS.

33 Bailey—S. R. Bailey & Co., 695 Boylston St.
 249-252 Buffalo—W. L. Russell Co., Motor Mart.
 320, 324 Columbus—Imperial Automobile Co., 182 Columbus Ave.
 123a, 124 Detroit—Anderson Electric Car Co., 903 Boylston St.
 153 Ohio—D. C. Tiffany Co., 135 Chestnut St.
 30 Rauch & Lang—Peerless Motor Car Co. of N. E., 660 Beacon St.
 5, 9 Waverley—J. W. Bowman Co., 91 Massachusetts Ave.
 108, 109 Woods—Whitten-Gilmore Co., 620 Commonwealth Ave.

STEAM PLEASURE CARS.

21 Stanley—Stanley Motor Carriage Co., Newton, Mass.

CYCLECARS, LIGHT CARS, ETC.

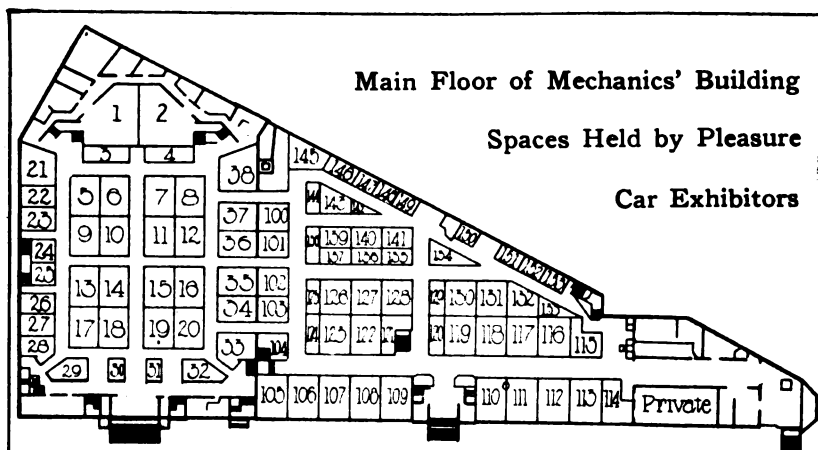

256 Herreshoff—Herreshoff Motor Sales Co., Troy, N. Y.
 313 LaVigne—C. J. Fischer Co., 233 Massachusetts Ave., Cambridge, Mass.
 215 Mercury—A. E. Kenney, 75 Haverhill St.
 334 Merz—Merz Cyclecar Co., Indianapolis, Ind.
 234 Trumbull—Rockledge Garage, Yonkers, N. Y.
 255 Twombly—H. Ross Maddocks Co., 175 Pleasant St.
 215 Victor—A. E. Kenney, 75 Haverhill St.

MOTORCYCLES.

527, 528 Excelsior—Hub Cycle Co., 14 Portland St.
 349 Harley-Davidson—Harley-Davidson Motor Company, 74 Huntington Ave.
 527, 528 Henderson—Hub Cycle Co., 14 Portland St.
 319 Indian—George N. Holden, 188 Massachusetts Ave.
 328 Jefferson—Jefferson Motorcycle Agency, 150 Massachusetts Ave., Arlington, Mass.
 350 Pope—New England Motorcycle Co., 178 Columbus Ave.
 321 Thor—Thor Motorcycle Co., 356 Columbus Ave.
 340 Yale—Puritan Motor Co., Boston.

HOW ACCESSORIES WILL BE DISPLAYED.

- 557—A. C. C. Oil Company, Providence, R. I., Acco lubricants.
- 550—Acme Torsion Spring Company, 998 Boylston street. Acme torsion springs, shock absorbers.
- 539—Aetna Life Insurance Company, 4 Liberty square. Insurance.
- 558—Ajax Trunk & Sample Case Company, New York City. Trunks, etc.
- 426—American Express Company, 43 Franklin street. Information booth.
- 307, 308—American Lava Company, Chattanooga, Tenn. Alco burner tips.
- 506, 509—American Motor Appliance Company, 69 Washington street. Blazer horns, etc.
- 446—American Storage Battery Company, Albion street, Cambridge, Mass. Harvard storage batteries.
- 561, 562—American Tire Company, Montello, Mass. American airless tires.
- 501—Arnold, N. B., Brooklyn, N. Y. Slik up specialties.
- 325—Auto Electric Trouble Station, 1074 Boylston street.
- 406—Automatic Appliance Company, 172 Columbus avenue. Boston starters for Ford cars, Casgrain speedometers, etc.
- 222—Automatic Tire Rest Company, Kansas City, Mo. Giant automatic jacks.
- 427—B & R Shock Absorber Company, Philadelphia, Penn. B & R shock absorbers.
- 305—Baker, W. A., Melrose, Mass. Marvel combination sets.
- 356bb—Barnstead Water Still Company, 51 Chardon street. Specialties.
- 504—Bascom, George R., 224 Columbus avenue. Basco Ford exhaust horns, Truffault-Hartford shock absorbers, Wasson concentric piston rings, etc.
- 328—Baxter Side Car Company, Toledo, O. Baxter side cars.
- 511—Blodgett & Johnson, 421 Tremont street. Sundries.
- 553—Bonner Company, D. Henry, 96 Plympton street, Cambridge, Mass. Tremo horns, etc.
- 619—Boston Tire & Rubber Company, 182 Friend street. Nassau tires, Thermoid reliners, etc.
- 432—Bowser & Co., S. F., 141 Milk street. Bowser storage systems.
- 449—Boyd, F. Shirley, 903 Boylston street. R. I. V. ball bearings, Multibestos brake lining, J. H. S. shock absorbers.
- 522—Braender Rubber & Tire Co., New York City. Braender tires.
- 525—Brock Rubber Company, A. S., 122 Milk street. Hose and rubber specialties.
- 307, 308—Burlington & Co., C. A., Berkshire, N. Y. Burlington folding chairs.
- 555—Burn Boston Battery & Manufacturing Works, Cambridge, Mass. Burn Boston batteries.
- 410—Calnan, James P., West Upton, Mass. Calnan tire removers.
- 513—Campbell Company, A. S., 284 Commercial street. Cello searchlights, battery cases, hot water bottles, etc.
- 360, 364—Cape Cod Power Dory Company, Wareham, Mass. Marine motors.
- 425—Cataract Tire & Rubber Company, 66 Hereford street. Cataract tires.
- 417—Champion Spark Plug Company, 954 Tremont street. Spark plugs.
- 243-247—Chandler & Farquhar Company, 419 Atlantic avenue. Machine tools, etc.
- 310a—Colby, C. B., Boston. Floral decorations for cars.
- 540—Collins, George, 280 Columbus avenue. Tubes, casings, boots, etc.
- 500—Columb Tyres Import Company, New York City. Prowodnik tires.
- 450—Combination Tail Light Company, Boston. Combination electric tail light and number holder.
- 541, 542—Connell Co., W. J., 171 Massachusetts avenue. Schebler carburetors, Elite jacks, Edmunds & Jones lamps, Gabriel horns, Gabriel rebound snubber, Spar-ton horns, fan belts, etc.
- 408—Cox Company, A. W., Heywood street, Cambridge, Mass. Automobile and motor truck parts and supplies.
- 603—Cox Brass Manufacturing Company, Albany, N. Y. Cox rebound E-Zers, Cox combined welding and carbon remover, Coxadusto shock absorbers, etc.
- 531—Cutter, Frank J., 30 Amherst street, Cambridge, Mass. Automobile bodies.
- 306—Dahl Manufacturing Company, New York City. Master slide rules, etc.
- 522—Dayton Tire Company, 589 Boylston street. Dayton airless tires.
- 238—Dean Auto Devices Company, Chicago, Ill. Dean Fordons, Dad wheel push buttons.
- 505—Deery & Co., D. H., Bridgeport, Conn. Deery electric motor truck tires.
- 304—Dodge, Frank, 420 Boylston street. Aiken revolving automobile lamps.
- 556—Eagle Oil & Supply Company, 104 Broad street. Eageline No-Karbon oils.
- 429—Earnsdale Worsted Company, Clinton, Mass. Moto-kloth upholstery materials.
- 336—Eastern Oil Tank Company, Lowell, Mass. Gasoline and oil storage systems.
- 358—Evenson & Sons, J., Camden, N. J. Jesco soaps and polishes, screw drivers, hydrometer syringes.

 602 B—Zetterman Machinery Company, 6 Beacon street. Specialties.

RUSSIAN TIRE FACTORY.

Something Concerning the Plant at Riga, Where Prowodnik Tires Are Made.

An accompanying illustration presents a portion of the Prowodnik tire factory at Riga, Russia, where the labor conditions are held to be such that the product is not burdened with the necessity for speed in manufacture, and where in many cases father and son have worked for generations. This tire is now being sold in America, through the Columb Tyres Import Company, New York City, for which the Park Square Motor Mart Garage is Boston distributor.

It is maintained that Prowodnik tires were designed especially to meet the road conditions found in Russia, and, as most Americans are aware, these are by no means ideal. The peculiar formation of the reverse herring-bone tread, called the Columb, is said to have been worked out theoretically by Russian engineers, after which it was given a number of practical tests on the Russian steppes, before finally being placed on the market.

As will be noted, the factory is of extensive proportions, and it is explained by the company that the manufacturing conditions are ideal. The tires are made of what is regarded as the correct proportion of Para rubber and fabric, and extreme care is taken in building up the casing, so as to give the core the same elasticity as the tread. The sidewalls are held to be of excep-

tional thickness, and the construction at the bead is with a view to eliminating rim-cutting. The line will be displayed at the Boston show.

The Mercury Manufacturing Company, Chicago, maker of Mercury trucks, finds that the similarity of its name to that of the Mercury Cyclecar Company of Detroit, maker of the Mercury cyclecar, has occasioned some little confusion, since it is in receipt of considerable correspondence regarding the cyclecar. The Chicago

Partial View of the Plant at Riga, Russia, Where Prowodnik Tires Are Made to Meet Russian Road Conditions.

concern has been producing a 1000-pound delivery wagon for the past four years, and is in no way connected with the Detroit company.

Announcement is made that the Van Sicklen Publishing Company, Monadnock building, Chicago, has purchased Motor Field, heretofore published by G. A. Wahlgren in Denver, Col., and that the publication office will be transferred to Chicago.

BIG GAIN IN EXPORTS DURING 1913.

COMPLETE returns from the bureau of foreign and domestic commerce, Department of Commerce, Washington, D. C., for the year, 1913, show a tremendous gain in the value of automobiles and parts exported by American manufacturers, over the preceding year. The total value of cars shipped abroad during 1913 was \$27,029,451, as against \$23,703,989 for 1912, and \$15,924,361 for 1911. This is a gain of 12.5 per cent. over 1912 and 41 per cent. over 1911. If the value of the parts be added, the figures for 1913 are \$33,299,567, as against \$28,308,118 for 1912 and \$19,178,584 in 1911, or a gain of 15 per cent. over 1912 and 42 per cent. over 1911.

statistics supplied by the government do not give the number of commercial cars shipped into this country, but the total of all cars was 492.

The tabulation also shows the comparative results for December in 1912 and 1913, indicating a substantial gain in exports. Rather more interest attaches to the imports in this connection, however, because of the new tariff law, which went into effect in October. The figures for December show a reduction of nearly 60 per cent. in the value of cars shipped into the country for that month in 1913 as compared with the same month in 1912.

It is somewhat surprising to note that the val-

ANNUAL REPORT CONCERNING IMPORTS AND EXPORTS.

IMPORTS.

Totals.....	2,013	\$2,060,812	2,389	\$2,152,144	15,807	\$15,924,361	23,720	\$23,703,989	26,889	\$27,029,451
Parts (not including engines and tires)	367,364	540,042	3,254,123	4,604,129	6,270,116
Grand totals.....	..	\$2,428,176	\$2,692,186	\$19,178,484	\$28,308,118	\$33,299,567

During the same period the value of cars imported into the United States was \$1,154,873, as against \$1,999,587 for 1912 and \$2,098,481 for 1911. This means a loss of 42 per cent. over 1912 and 45 over 1911. If the value of the parts be added the figures for 1913 are \$1,602,811, as against \$2,275,406 for 1912 and \$2,446,248, showing a loss of 25 per cent. over 1912 and 26 per cent. over 1911.

The detailed figures are presented in an accompanying table, but these do not include the number of passenger and commercial vehicles separately. There were 25,880 of the former shipped abroad, at a valuation of \$25,342,644, and 1009 commercial cars, valued at \$1,686,807. The

uation of parts brought in during December, 1913, was more than 10 times as great as for the same month in 1912. It will be remembered in this connection that the duty on finished parts was reduced in the new tariff law from 45 per cent. to 30. Whether or not this has any bearing on the official government report is, perhaps, too early to determine.

It may be stated that the 88 commercial vehicles, valued at \$100,660, were shipped abroad during December, 1913, as against 87, valued at \$156,350, during the same month in 1912. The comparison on passenger cars is as follows: December, 1912, 2301, valued at \$2,051,484; 1913, 1926, valued at \$1,895,462.

NEW TIRE POLICY.

Goodyear Will Make Adjustments Only for Faulty Workmanship and Material.

According to information from Akron, O., the Goodyear Tire & Rubber Company of that city has adopted a new policy with respect to making adjustment for tires made by it. Under the new plan, it is understood that adjustments will be made only for failure due to faulty workmanship or material, and none will be made where it is certain that the trouble is due to stone bruises or other causes resulting from careless driving.

It is also stated that the Goodyear company has formally taken over the manufacture and sale of Standard tire protectors as a part of its automobile tire department. This is a separate tread which covers the sidewalls as well as the tread, and when applied remains firmly in place without additional fastening.

TWO SHOWS IN CINCINNATI.

First Week Devoted to Pleasure Cars and Three Days for Truck Exhibitors.

The fourth annual show of the Cincinnati Automobile Dealers' Association was opened in Music hall, Cincinnati, O., Feb. 21. This year the show is divided into two sections, this first week being devoted entirely to pleasure cars and their accessories, while the first three days of the week beginning March 2 will witness a separate display of motor trucks and business wagons.

It may be added that this is the second exhibition of cars to be made in that city this year, the first having come to a close Feb. 14, under the auspices of the Cincinnati Automobile Trade Association. This also was responsible for a court action, inasmuch as the Junglas Automobile Company displayed Overland cars in the first show. The court held that, as this company was a member of the Cincinnati Automobile Dealers' Association in good standing, it could not be prevented from making display at that organization's exhibition. This is a point of some little interest, since many dealers' associations throughout the country have rules similar to that in Cincinnati, which seek to prevent members from making display in shows held by other organizations.

The attendance at the second show was decidedly large, and much business was transacted. The list of exhibitors included the following:

Chas. Behlen's Sons, Detroit electric; Cincinnati Automobile Company, Stutz, Pope-Hartford; Citizens Motor Car Company, Packard; Fischer Auto & Service Company, Locomobile, Chalmers; Ford Motor Car Company, Ford; Franklin Motor Car Company, Franklin; Hanauer Automobile Company, Pierce-Arrow; Hellman Motor Car Company, Haynes; Herschede Motor Car Company, Rauch & Lang electric; Imperial Motor Car Company, Stearns-Knight, Baker electric; Junglas Automobile Company, Overland; Kentucky Motor Car Company, Oakland; Kruse Motor Car Company, Marmon; Leyman-Buick Company, Buick; Geo. C. Miller Sons, Cole, Standard electric; Ratterman Motor Car Company, Maxwell; Chas. Schlear Motor Car Company, Hupmobile, Apperson; Stevens-Duryea Company, Stevens-Duryea; Towle-Cadillac Company, Cadillac; Welbon Motor Car Company, Hudson.

The following exhibitors were listed for the commercial vehicle display:

Cincinnati Motor Truck Company, Universal; Citizens Motor Car Company, Packard; Hanauer Automobile Company, Pierce-Arrow; Hellman Motor Car Company, Commerce; Kruse Motor Car Company, Kelly; Leyman-Buick Company, Buick.

FIRST AID TREATMENT.

West Side Y. M. C. A. Automobile School Adopts an Innovation in Instruction.

The automobile school conducted by the West Side Y. M. C. A., Eighth avenue and 57th street, New York City, is one of the oldest in the country, and it is not surprising to learn that it has adopted another innovation, which is expected to meet with the same high degree of approval as other plans which have been put into force by this institution. In the future, all graduates of this school will be in a position to render first aid treatment to any person who may be injured as the result of unavoidable accidents, or otherwise.

Dr. Theron W. Kilmer, formerly surgeon of the National Guard of New York State, will be in charge of the class in first aid to the injured. Several weeks ago students in the automobile school were informed of the plan to add this course and the statement was greeted with decided approval. Dr. Kilmer, who is recognized as a specialist in this field, volunteered his services.

The course will lay special emphasis on the treatment of gasoline burns, bruises, broken limbs, etc. Dr. Kilmer asserts that every automobilist should be an expert in first aid treatment and that he should carry a first aid kit in his machine as a part of his regular equipment. He adds that most men are fortunate enough never to be injured or to injure anyone else, but no man can tell when he will need such knowledge.

The first dirt track race meet of the season will be held at Hot Springs, Ark., March 9.

CARS SEEN IN BOSTON FOR THE FIRST TIME.

ALLEN 40.

Moderately Priced Car with Two and Five-Passenger Bodies.

The Allen 40 is manufactured by the Allen Motor Company, Fostoria, O., and was designed to meet the de-

mand for a moderately priced car, having those refinements and the high grade material characteristic of machines listing at a higher figure. Two bodies are fitted to the one chassis, a five-passenger touring and a two-passenger roadster. These have attractive lines and are complete in appointments.

The four-cylinder motor, clutch and gearset are a unit, the first named having a bore of 4.125 inches and stroke of five. Carburetion is by a Schebler and ignition by Splittdorf magneto. The wheelbase is 118 inches and the tires 34 by four. The driver is at the left. The equipment includes the Auto-Lite systems of electric lighting and starting.

CHANDLER SIX.

Light Weight, Big Mileage and Moderate Price Among Its Features.

Organized about a year ago, the Chandler Motor Car Company, Cleveland, O., is producing the Chandler Six, which is stated to weigh less than 3000 pounds when fully equipped, and its designers, who have long been identified with the industry, claim 16 miles to a gallon of fuel and 700 miles to a gallon of lubricant. Its moderate price is another feature of the product.

The motor is constructed in the factory of the company, and is of the L head type, with the six cylinders cast in triplets. It is in the long stroke class, the bore being 3.375 inches and the stroke five. One of the features of the power plant is the use of extensions from the crankcase, which fit to the frame, obtaining weather proof qualities and eliminating the usual undershield.

The oiling system is contained within the motor, a rotary pump located in the engine pan pumping the lubricant to all main bearings and working parts. The individual trough

system is utilized. The transmission is a three-speed selective gearset, enclosed within the case housing the multiple disc clutch and all bearings are F. & S. imported annular. The lighting and motor starting system is a Westinghouse.

HOWARD SIX.

Utilizes Unit Power Plant and Two Separate Ignition Systems.

The first models of the Howard Six were introduced about the time of the 1913 Chicago show. The latest models are manufactured by the Lexington-Howard Company, recently organized in Connersville, Ind. Only one chassis is produced, to which a two-passenger roadster and a seven-passenger touring car body are fitted. Particular attention is drawn to the large baggage carrying compartment in the rear deck of the roadster.

The motor is an L head type, with the six-cylinders cast in triplets. The bore is 4.125 inches and the stroke 5.25. Ignition is by two separate systems, an Atwater Kent Unisarker with automatic spark advance and LBA battery, and a Boston high-tension spark magneto. Another feature is the use of a multiple exhaust manifold.

by means of which the exhaust from three forward cylinders is taken through a separate compartment from that of the other three. The clutch is a cone, and the selective transmission affords three speeds forward and reverse. The driver is at the left with central control levers. The wheelbase is 130 inches.

PACKARD 4-48.

An Addition to the Line Announced for the Boston Show.

Of course, the Packard line, made by the Packard Motor Car Company, Detroit, is not new to the Boston show, but the maker has decided to reserve the initial display of the new 4-48 until this time, this particular model having been announced since the holding of the New York and Chicago exhibitions. It is a six-cylinder chassis, embodying all the features of the 2-38, with the added advantage of more surplus power. The motor has bore of 4.5 inches and stroke of 5.5. The wheelbase is 144 inches and the tires 37 by five inches. The body designs are the same as with the 2-38, with the addition of the salon touring car, in which the front seats are of separate construction, and a special all-weather design, made by the Springfield Metal Body Company, Springfield, Mass.

CAR-NATION MODEL C.

Produced Also in Two-Passenger Designs in Light Weight Class.

The Car-Nation is the product of the American Volturette Company, Detroit. It made its initial appear-

ance just before the advent of the cyclecar in this country, and two of its models have been classed as cyclecars, although they do not come strictly within the definitions of such machines recently adopted. Model A is a two-passenger roadster, weighing 1050 pounds, and model B is a tandem two-seater, weighing 1150.

Model C is a touring car, seating four persons. All chassis utilize the same motor, which is a four-cylinder, L head unit, cast en bloc, with bore of 3.375 inches and stroke of 3.75. Power is transmitted through a multiple disc clutch and selective three-speed gearset. The wheelbase is 104 inches and the tires 30 by three inches, fitted to wire wheels. A distinctive feature is the use of a pointed radiator.

BRISCOE.

A Car Which Was Originated in France by American Engineers.

The Briscoe had its origin in France, where it is made by the Briscoe Freres, composed of Benjamin and Frank Briscoe, two men who have long been identified with the industry in this country. It is being produced in America by the Briscoe Motor Company, with executive offices at 7 East 42nd street, New York City, and factory in Jackson, Mich. But one chassis design is manufactured, this being fitted with a two-passenger roadster and a five-passenger touring body.

The four-cylinder motor is a block casting of the L head type, with bore of 3.2 inches and stroke of 5.125. Power is transmitted through a cone clutch and a three-speed selective gearset. The wheelbase is 106 inches and wire wheels are employed. A distinctive feature of the design is the use of a single headlight mounted directly over the radiator at the extreme front, practically flush with it.

KEETON SIX-48.

A Machine of the So-Called French Type, with Five Body Designs.

The American Volturette Company, Detroit, is also producing the Keeton Six-48, a high grade car, which is held

to possess many of the characteristics of the so-called French type. This is particularly noticeable in the use of a hood of foreign design, incorporated with which is the radiator directly in front of the dash. Five body designs are fitted to the one chassis, these being a two-passenger roadster, seven-passenger touring, three-passenger convertible, five-passenger convertible and seven-passenger berline-limousine.

The motor is an L head type, with its six cylinders cast en bloc. The bore is four inches and the stroke five. Ignition is by Elsemann dual high-tension magneto with automatic spark advance. Power is transmitted through a multiple disc clutch and four-speed selective gearset. The wheelbase is 136 inches and the wire wheels are fitted with 34 by 4.5-inch tires. The equipment is most complete, including the Jesco electric starting and lighting system.

WILLYS-KNIGHT.

Changes Adopted Since Car Was Seen Last Year as Edwards-Knight.

Although the Willys-Knight is in many respects the same as the Edwards-Knight, which was shown last year at Boston, the rights to manufacture this machine having been taken over late in 1913 by John N. Willys of the Willys-Overland Company, several changes have been made, largely in the nature of refinements. Only one chassis is produced, to which a roadster and a five-passenger touring body are fitted, in the old Garford plant of the Willys-Overland Company at Elyria, O., where the motors also will be made.

The four cylinders are cast in pairs, with bore of four inches and stroke of 5.5. The only changes in the motor are in the use of a specially designed Stromberg carburetor and a new method of lubrication. The latter is designated as an automatic system, by means of which the supply of oil is proportioned to the speed of the motor, through a throttle connection. The pump is of the plunger type.

Distinctive features, which have

been retained, include the use of the oil submerged worm gear rear axle, Lanchester cantilever type rear spring suspension and wire wheels. The wheelbase is 120 inches and the tires 36 by 4.5 inches. The equipment is complete in every detail.

SAXON ROADSTER.

An Interesting Light Weight Car of Simplified Construction.

While there is bound to be more or less confusion from the indiscriminate use of terms, the Saxon roadster, made by the Saxon Motor Company, Detroit, rightfully belongs in the automobile class. It is in no sense a cyclecar, despite the low power of its motor and its generally simplified design and construction. The equipment includes a top and windshield, wire wheels and everything essential.

The motor is rated at 11 horsepower. It is of the L head type, with fully enclosed valves. The four cylinders and crankcase are cast en bloc, with bore of 2.625 inches and stroke of four. Lubrication is said to be by an entirely new method, which is termed a vacuum splash, oil being circulated and held at a constant level without a single moving part. The carburetor is a Mayer. Ignition is by the Atwater Kent Unisparker and six dry cells. The clutch is an asbestos lined, dry plate, five-disc type, and the progressive transmission affords two forward speeds and

reverse. The wheelbase is 96 inches and the wire wheels are fitted with 28 by three-inch tires.

NATIONAL SIX.

Innovation of Well Known Maker Will Be New to Boston Display.

Although the product of the National Motor Vehicle Company, Indianapolis, Ind., has been displayed at previous Boston shows, this concern recently announced a new six, which will be exhibited for the first time in New England at the forthcoming display. Heretofore National cars have been presented only in four-cylinder models.

The motor is cast en bloc, with bore of 3.75 inches and stroke of 5.5. Lubrication is by splash with pressure feed to the main bearings and timing gears. The ignition system is dual, magneto and battery. The cone clutch may be removed without disturbing the transmission. Another feature is the use of an adjustable clutch pedal, while a radical departure is found in the adoption of a cantilever type rear spring, so arranged that the entire end thrust of the car is taken through this, probably the first attempt to utilize a cantilever spring as a propulsive member. New body designs are also supplied with this model.

JEFFERY SIX.

Maker of Former Rambler Machine Also Lists the Jeffery Four.

The Thomas B. Jeffery Company, Kenosha, Wis., well known in the industry as the maker of the Rambler,

has decided to perpetuate the name of the founder of the company by designating its product in the future as the Jeffery. There are two models, a four and a six-cylinder, the latter of which is entirely new. This will be produced in five body types, roadster, four and six-passenger touring, sedan and limousine.

The motor is with cylinders arranged in pairs. The bore is 3.75 inches and the stroke 5.25. One of the features is the water jacketing of the intake manifold, and it is also noted that the undershield has been eliminated, being replaced by plates extending from the frame to the crankcase. Between the gearset and the cone clutch is a leather universal coupling, consisting of six rings about six inches in diameter, and .1875 inch thick, which is employed to take care of any misalignment, and it is stated that shocks and stresses are avoided in the clutch action.

MOLINE-KNIGHT.

Utilizes Block Casting and Thermo-Syphon Cooling System.

The Moline Automobile Company, East Moline, Ill., is the first concern in this country to employ a Knight sliding sleeve valve motor with cylinders cast en bloc. It also has departed from the usual practise with these motors in employing thermo-syphon method of cooling. By reason of the fact that the result of the recent remarkable endurance test of the Moline-Knight engine in the laboratory of the Automobile Club of America has had such wide circulation, it would seem superfluous to make particular reference to this motor at this time.

The Moline-Knight is produced in one chassis and body model, this being a five-passenger touring car, which is ironed for two extra seats, making it readily convertible into a seven-passenger machine. Many refinements in design and construction are noted, these including a longer wheelbase of 128 inches; larger tires (36x4.5), and complete equipment.

LEXINGTON FOUR.

Product of a New Company Redesignated, but Bears Its Old Name.

Although the name Lexington is by no means new to the industry, the four-cylinder Lexington car present-

ed by the recently incorporated Lexington-Howard Company, Connersville, Ind., really is a new design. It was first announced during the recent Chicago show, and will be produced as a five-passenger touring car and a roadster. A feature is the use of patent adjustable seats, and it may be added that the tire carrier is made integral with the chassis frame.

The motor is of the L head type, with bore of four inches and stroke of five. It follows so-called standard practise in the main, but an unusual feature is the incorporation of the Moore exhaust, wherein the waste gases from two of the cylinders are carried away in a separate branch of the manifold from that which takes care of the other two cylinders. Ignition is by the Atwater Kent Unisparker, utilizing an LBA storage battery. Carburetion is by a Schebler. Cooling is by centrifugal pump. The clutch is a cone and the transmission affords three forward speeds and reverse. The wheelbase is 114 inches.

KING MODEL B.

Latest Product of a Pioneer Designer Utilizes Cantilever Springs.

Charles B. King, who designed the King cars, made by the King Motor Car Company, Detroit, drove his first horseless carriage in the streets of Detroit in 1894. This was produced from designs drawn by him the previous year. The latest King, model B, is characterized by the maker as a low priced car, but not cheap, and it is maintained that it represents sturdiness and perfect adjustment in every feature. Two bodies, a roadster and a five-passenger touring, are fitted to the single chassis.

The motor is a four-cylinder, L head unit, cast en bloc, with bore of 3.875 inches and stroke of five. Lubrication is by splash with pump circulation. Ignition is by a dual system with Briggs magneto and one set of plugs. The carburetor is a Stromberg. Cooling is by thermo-syphon, aided by a six-blade fan. The clutch is a multiple disc, faced with Raybestos. The selective transmission af-

fords three forward speeds and reverse. The wheelbase is 112 inches and the tires, 33 by four inches. A particular feature of the construction is the use of a cantilever rear spring suspension.

HERFF-BROOKS SIX.

This and a Four Made Their Debut at the Chicago Show.

Among the strictly new machines of the industry are the two Herff-Brooks models, which made their initial appearance during the recent Chicago show. They are made by the Herff-Brooks Corporation, Indianapolis, Ind., and are presented in four and six-cylinder types, both with roadster and touring car bodies.

The four is with an L head motor, cast en bloc, with bore of 4.125 inches and stroke of five. The crankshaft is carried on five bearings and the valves are completely enclosed. Lubrication is by splash, with gear pump circulation. The clutch is a leather faced cone, and the gearset has three forward speeds and reverse. The wheelbase is 116 inches and the tires are 34 by four inches.

The six-cylinder motor is also an L head type, with cylinders cast separately. The bore is four inches and the stroke 4.5. Except that the crankshaft is carried on seven bearings, the details of construction are the same as with the four. The wheelbase is 124 inches and the tires,

34 by four inches. Both models are completely equipped, including an electric lighting and motor starting system.

PREMIER WEIDELY.

Employs New Type of Motor of the Valve-in-the-Head Design.

Inasmuch as the motoring public is unusually interested in new types of motors, those who visit the Boston show will not care to miss the new Weidely poppet valve motor, of the valve-in-the-head type, fitted to 1914 Premier cars, although the product of the Premier Motor Manufacturing Company, Indianapolis, Ind., is not new to New England. This is a six-cylinder engine, cast en bloc, and while the type is not new in itself, the application of the principle is a decided innovation. The camshaft is located directly above the ends of the valve stems, and a very light steel finger accomplishes the service usually performed by rocker arms. It is maintained that this construction makes for an exceptionally quiet motor, and one that is economical of fuel.

KISSELKAR 40.

Two Six-Cylinder Machines Also Included in This Maker's Line.

This is not the first year in which the KisselKar, made by the Kissel Motor Car Company, Hartford, Wis.,

has been displayed at Boston, but the line was not on view in 1913. It is anticipated that newer models than those described herein will be announced during the forthcoming show. At present, however, the line includes the 40, shown herewith, and two sixes, 48 and 60.

The motor of the 40 has bore of 4.5 inches and stroke of 5.25, which are the same as the dimensions for the 60. The 48 has motor with bore of 3.75 inches and stroke of 5.5. All models utilize a leather faced cone clutch and a four-speed selective transmission. The wheelbase of the 40 is 121 inches, that of the 48, 132 inches, and that of the 60, 142. The tires are 36 by four, 36 by 4.5 and 37 by five, respectively.

In body designs the KisselKar line is most complete, the 40 being equipped as a roadster, touring car and coupe; the 48 as semi-racer, touring car and limousine, and the 60 as roadster, touring car and limousine. All models are completely equipped.

APPERSON 6-45.

Well Known Pioneer Manufacturer Adds a Six-Cylinder Model.

While Apperson cars, made by the Apperson Bros. Automobile Company, Kokomo, Ind., have been seen at previous Boston shows, they were not displayed a year ago, and this will be the first opportunity to view the new 6-45. The line also includes the 4-45, a four-cylinder model. The latter is fitted with roadster, touring, coupe and sedan bodies, while the former is presented in the roadster and touring types.

The motor on the new six is of the T head type, cast en bloc, with bore of 3.75 inches and stroke of 5.5. The clutch is a contracting band, and the selective gearset affords three forward speeds and reverse. The wheelbase is 120 inches for the roadster and 128 for the touring car. Tires are 36 by four inches.

The motor of the 4-45 has bore of 4.5 inch and stroke of five. The wheelbase is 120 inches and the tires 34 by four inches. The constructional details are the same.

SHOWN FOR THE FIRST TIME THIS YEAR.

LENOX SIX.

Boston Concern Is Continuing This and the Four-Cylinder Model.

Unique in its position as the only automobile manufacturer with plant located in Boston, the Lenox Motor

Car Company naturally would be expected to take a prominent part in the annual Boston show. The product was designed to meet the requirements of New England people, and it has made its appeal very largely to the prospective purchasers in that district.

The line comprises a four and a six, and in the main these two chassis do not differ materially in design and construction. The four-cylinder motor has bore of 4.25 inches and stroke of 5.5, while the six has bore of four and stroke of five. The design follows standard practise throughout, with cone clutch and three-speed transmission. The wheelbase of the four is 118 inches and of the six, 130 inches. Tires are 36 by four and 36 by 4.5 inches, respectively.

STANLEY MODEL 710.

The Only Exponent of the Steam Vehicle at Any of the Shows.

Another maker that has been represented at practically all of the Boston shows is the Stanley Motor Carriage Company, Newton, Mass., maker of Stanley steam cars. There was a time when the steam machines were decidedly numerous at Boston shows, but during the past few seasons the field has been held exclusively by the Stanley, which has not been exhibited at any of the other big shows of the year.

The Stanley is made in three models, each with touring car bodies. The model 710, illustrated, has a two-cylinder, double-acting engine, with bore of four inches and stroke of five. The other engines are the same in design, but that of the model 607 has bore of 3.25 inches and stroke of 4.25, and that of the model 811, bore of 4.5 and stroke of 6.5. The wheelbases are: Model 607, 112 inches; 710, 120 and 811, 134. Tires are 32 by four, 36 by four and 36 by 4.5, respectively.

Model 710 is listed as a touring car, and with a roadster on the same chassis is known as model 712. Model 607 is a touring car, and as a roadster it is designated as model 606. Model 811 is listed as a seven-passenger touring car only, although commercial vehicle bodies are fitted to this same chassis.

FORD MODEL T.

The Universal Car Is Continued in Three Body Styles.

For some years, the only automobile display of national prominence in which Ford cars, made by the Ford Motor Company, Detroit, have been exhibited, has been the annual Boston show. During the 11 years in which this make of machine has been in the market, its general sale in all parts of the world has earned for it the title of the Universal car. For 1914 it is continued in three body styles, roadster, touring car and town car.

The motor is a four-cylinder unit of the L head type, cast en bloc, with bore of 3.75 inches and stroke of four. The clutch is a multiple disc, and the transmission a special Ford spur planetary type. The wheelbase is 100 inches and the tires are 30 by three inches forward and 30 by 3.5 rear.

The Ford must be regarded as a standardized car, in that the Ford company has not seen fit to make changes in design or construction. The line is almost too well known to require extended comment.

INTER-STATE.

Expected That Product of New Concern Will Be Disclosed.

As noted elsewhere in this issue, the Inter-State Motor Company has been organized to take over the production of Inter-State cars, heretofore conducted by the Inter-State Automobile Company, Peru, Ind. It is stated that this new concern will produce an entirely new model, although nothing definite relative to this plan has been made public. It is anticipated that these new cars will be seen for the first time during the forthcoming display in Boston, which will be the initial appearance of Inter-State machines at a show this year.

In connection with the new models, it is understood the design which was prepared by the old concern for the 1914 season will be continued. Bore of four inches and stroke of five. This is with a six-cylinder motor of the L head type, cast en bloc, with the wheelbase is 132 inches, and the tires 36 by 4.5. This is produced with a five-passenger touring body.

MOYER MODEL G.

Maker Also Produces a Four-Cylinder Chassis with Three Bodies.

This is the fifth year that the Moyer cars have been on the market, and the second in which they have

been displayed at the Boston show. They are made in two chassis designs by H. A. Moyer, Syracuse, N. Y. The design and construction are similar with each. The six is fitted with touring and phaeton bodies, and the four with roadster, touring and phaeton.

Both motors are of the T head type, cast in pairs, with bore of 4.5 inches and stroke of five. The clutch is a cone, and the selective transmission affords three forward speeds and reverse. Special attention is directed to the spring suspension, the rear springs being fitted with equalizers at both ends, a method which is claimed to balance the load at all times. The wheelbase of the six is 135 inches, and the tires 35 by 4.5. The wheelbase of the four is 120 inches, and the tires 34 by four.

KNOX 46.

Well Known Pioneer Maker Is Featuring Prince Henry Body.

Practically ever since there was a Boston show, the Knox Automobile Company, Springfield, Mass., has been represented. This year it is the only display of national importance at which Knox cars will be shown. The company manufactures four models, 44 and 45, four-cylinder, and 46 and 66, six-cylinder. Particular attention is drawn to the model 46, or little six.

In the main, the design and construction have not been changed, and the principal feature is the fitting of a new body, termed the Prince Henry, this being of the streamline type. The motor is of the valve-in-the-head type, with cylinders cast in pairs. The bore is 4.375 inches and the stroke 5.5. The wheelbase is 134 inches and tires 38 by 5.5.

The Knox 44 and 45 are four-cylinder chassis with motor of five-inch bore and 5.5-inch stroke. The wheelbase of the former is optional, while that of the latter is 126 inches. The Knox 66, or big six, has motor of the same bore and stroke, and wheelbase of 134 inches. All Knox models have electric lighting and starting.

CYCLECARS MAKING THEIR BOSTON DEBUT.

TWOMBLY.

Utilizes Piston Valve Motor and Made in Two Body Styles.

The Twombly, made by the Twombly Car Corporation, New York City, with factories at Nutley, N. J., and

Sharon, Penn., is classed as a light car. It is made in two body designs, one a tandem two-seater and the other a delivery wagon. The wheelbase is 100 inches, the tread 38, and the weight about 600 pounds.

The motor is a special, Twombly silent piston valve type, with four cylinders cast en bloc, rated by the maker at 15 horsepower. This is water-cooled by the thermo-syphon system. The friction transmission is also of special design, termed a three-step, with two-speed drive shaft and single chain drive to the rear axle, thus affording six forward speeds and two in reverse. The wire wheels carry 28 by 2.5-inch tires. The equipment is very complete.

MERZ.

An Indianapolis Product Designed by Well Known Racing Driver.

The Merz, produced by the Merz Cyclecar Company, Indianapolis, Ind., is another true cyclecar, and it is of particular interest from the fact that it was designed by Charles Merz, well known as an automobile racing driver with National cars. Two body designs are offered, a tandem two-

seater and a parcel delivery wagon. The wheelbase is 84 inches and the tread 40.

The motor is a DeLuxe two-cylinder, air-cooled V type, with bore of 3.5 inches and stroke of 3.67. Drive is by shaft to a friction transmission, which provides four forward speeds and reverse, and thence by short V belt to the rear wheels. The wire wheels are fitted with 28 by three-inch tires.

A distinctive feature of the design lies in the use of a single headlight in the centre of the front, and almost flush with it. This front is a wire screen to allow free air circulation, and the screen, as well as the ventilation doors on the sides of the

hood, is removable to permit easy access to the motor. It may be added that the transmission is composed of a friction wheel with a fibre surface contacting with a steel driving disc. The friction clutch is supported on a cross member about amidships.

TRUMBULL.

Friction Driven Model That Is Classified as a Light Car.

The Trumbull, made by the American Cyclecar Company, Bridgeport, Conn., is fitted with a four-cylinder motor of such dimensions as to place it in the light car class. It is produced as a two-passenger roadster, with seats arranged side by side, and has a wheelbase of 80 inches, tread of 44, and weight of approximately 650 pounds. The car comes completely equipped, this including motor starter, electric lights, electric horn, etc.

The motor is a water-cooled unit of the L head type, with mechanically operated valves and with bore of 2.875 inches and stroke of four. The friction transmission affords four forward speeds and reverse, and final drive is by roller chains. The wire

wheels, which are of a special patented design and demountable, are fitted with 28 by three-inch tires.

VICTOR.

Another Light Car Model, Designed as a Two-Passenger Roadster.

The Victor is the product of the Victor Motor Car Company, Philadelphia, Penn., and is produced as a two-passenger roadster, with seats side by side. The motor dimensions are such as to place it in the light car class. The wheelbase is 98 inches and the weight about 800 pounds.

The motor is a four-cylinder, water-cooled, L head type, cast in pairs, with bore of 3.375 inches and stroke of 3.75. The clutch is a cone and the sliding gear transmission affords three forward speeds and reverse. Final drive is by shaft and bevel gear. The wire wheels are fitted with 30 by three-inch tires.

MERCURY.

A True Cyclecar Produced in Two-Passenger and Monocar Types.

The Mercury, made by the Mercury Cyclecar Company, Detroit, is a true cyclecar, with piston displacement

well within the limit set for such machines. It is produced in two body types, one providing for two passengers arranged tandem, and the other a monocar, a single-seated machine which is expected to make a direct appeal to business men. The wheelbase is 100 inches and the tread 36.

The motor is a DeLuxe, twin-cylinder, air-cooled V type, with bore and stroke of 3.5 inches. Power is transmitted by shaft and friction disc to a friction wheel on the countershaft, and thence by two V belts. Underslung springs are utilized both front and rear. The wire wheels carry 28 by 2.5-inch tires.

LAVIGNE.

Machine of the Light Car Type Fitted with Four Body Designs.

The LaVigne Cyclecar Company, Detroit, is producing the LaVigne, which comes under the light car classification of the Cyclecar Manufacturers National Association. It is provided with four body designs, a

two-passenger roadster, cabriolet, coupe and a parcel delivery wagon. Each of the pleasure vehicles is arranged to seat side by side. The wheelbase is 96 inches and the tread 50. The weight ranges from 650 pounds for the roadster to 800 for the delivery wagon.

The motor is a four-cylinder, air-cooled unit, cast en bloc, with bore of 2.375 inches and stroke of four. Power is transmitted by a sliding gearset affording two speeds forward and reverse, and shaft to a worm driven rear axle. The wire wheels are fitted with 30 by three-inch tires. Provision is made for starting from the seat.

RUSSELL-KNIGHT TEST.**Mea Magneto and Stromberg Carburetor Also Factors in Canadian Run.**

A 300-hour test of a Russell-Knight sleeve valve engine was completed in the laboratory of the University of Toronto, Ont., Feb. 10. This differed in a number of particulars from the 336-hour test to which the Moline-Knight engine was subjected in the laboratory of the Automobile Club of America in New York City the first of the year. It was started with a 24-hour run at 500 revolutions a minute, and this speed was increased 100 revolutions during each 24-hour period.

At the completion of the test the motor was completely disassembled and the following results are reported: The pistons, sleeves and cylinders were found to be round and true, and showed polish marks of perfect fitting. The exhaust ports of the cylinders were clear and clean. The exhaust ports of the sleeves showed about .03125 inch of carbon deposit on the edges. The piston heads had a slight carbon deposit around the edges, but tool marks were visible elsewhere. The cylinder heads were quite clean, small pieces of crust being in evidence here and there. The broad junk rings were well bedded in the sleeve walls. The bearings of the crankshaft, eccentric shaft, rods and wristpins were snug, and quite ready for car service. Most of the bearings bore a polish. The chain drive for the sleeves was slightly loose, but not in need of adjustment.

Throughout the test the Stromberg 1.75-inch carburetor was not adjusted, but was set with wide open throttle. The Mea magneto was changed with every increase in speed up to 1000 revolutions a minute, when its maximum advance was reached. Several spark plugs were changed.

PROTECTION FOR MOTORISTS.**Massachusetts Bonding & Insurance Company Presents Interesting Proposition.**

Motorists are endangered by the reckless use of highways, quite as much as pedestrians and others. Crowded traffic conditions often make it extremely difficult to avoid accidents of one kind or another. Most owners feel the need of the protection afforded by liability and property damage insurance.

The Massachusetts Bonding & Insurance Company, 77-85 State street, Boston, Mass., is directing special attention to its latest policy,

which has been described as 100 per cent. liability protection, and is particularly anxious to explain its features to automobile owners. Elsewhere in this issue will be found a coupon, which, if returned to the company properly filled out, will bring full details with reference to the individual car. T. J. Falvey is president of the company.

SMITH AIR VALVE.**Makes Easy the Pumping of Tires, Saving Both Time and Labor.**

The Smith Tire Valve Company, postoffice box 1965, Boston, is marketing the Smith easy pumping air valve, which is stated to require an almost imperceptible pressure to open in order to admit air into the inner tube of a pneumatic tire. It is designed to make easy the work of inflating shoes, and one of the qualities of it emphasized is that air is pumped into the tube from the beginning to the completion of the stroke of the pump. Ordinarily, the greater portion of the stroke is required to compress the air force open the conventional

Sectional View of Smith Easy Pumping Air Valve.

valve. The simplicity of the device is shown in an accompanying illustration. Not only does the Smith valve save time and labor, but it makes for tire economy in that its ease of operation insures that the owner will inflate the shoe to its proper pressure. It is a very compact device, being about an inch long and .375 in diameter. It is readily attached to the standard valve stem from which the cap and plunger are removed, as the Smith replaces these and performs their functions. The valves come in sets of five, are moderately priced, and are accompanied by a very liberal guarantee.

A movement is on foot looking toward a revival of the Fairmount Park road race, and the Philadelphia city councils have been asked for a permit to hold this classic during 1914.

HARTFORD DEALERS' DISPLAY.

Hold Seventh Annual Show in Park Casino Under Management of O. C. Wolfe.

The seventh annual show of the Hartford Automobile Dealers' Association, Hartford, Conn., was opened in the Park Casino, Feb. 21, for one week. The plans were somewhat different this year, since the list of exhibitors was limited to local dealers, which was made necessary by reason of the space available. The event was under the management of Owens C. Wolfe, assisted by the following committee: Bernard F. Smith, chairman; Herbert P. Seymour, Russell P. Taber, Lucius H. Elmer and Roger M. Spencer.

The color scheme was blue and white, and the treatment was colonial in character. The different spaces were set off by pillars surmounted by signs bearing the exhibitor's name, on top of which was perched an owl. The electrical display was particularly pleasing. The attendance throughout the early days of the week was such as to warrant the prediction of a new record, and dealers reported frequent sales. Among the exhibitors were the following:

Dillon Court Garage, Stutz; Buick Garage Company, Buick; Brown, Thomson & Co., Cadillac; Mfner Garage Company, Pierce-Arrow; Magna Automobile Company, Detroit electric; Universal Auto Company, Franklin; F. A. Law Machine Company, National; Edward Clark, Paige, Chandler; Palace Auto Service Company, Studebaker, Oldsmobile, Waverley electric; Packard Motor Car Company, Packard; George Knox, Peerless, Hudson; Russell Taber, Reo, Pullman; Capitol City Auto Company, Lozier; Pope Manufacturing Company, Pope-Hartford; Electric Auto Station, Ohio electric; W. H. Harris, Overland; R. N. Spencer, KisselKar; Stevens-Duryea Company, Stevens-Duryea; Elmer Automobile Company, Ford; J. N. Macdonald & Co., Velle; Chalmers Auto Agency, Chalmers; S. A. Foster & Co., Jeffery, White; F. F. Woolley, Baker electric; J. D. Parker, Hupmobile; Imperial Motor Car Company, Imperial, Grant; J. F. Trant, Imp cyclecar; Finch & Haynes, Henderson, Thor and Harley-Davidson motorcycles; Meyers Bros., Ivory novelties; Metz Auto Station, Metz; Chas. E. Miller, general line of accessories; A. N. Clark & Son, windshields; New England Garage Company, Chevrolet and J-M shock absorbers.

NEWARK'S BIGGEST SHOW.

Accessories Form Decidedly Important Section of Seventh Annual Display.

Outside of the shows in New York City, Chicago and Boston, probably no other display in this country this year will be able to make a record to compare with that of the accessory exhibitors at the seventh annual dealers' show in Newark, N. J., Feb. 21-28. There were 40 makes of pleasure cars and 19 of trucks on display, but the list of accessory exhibitors very nearly equalled both, there being 58 of them.

In many ways this exhibition was of decided

importance. Aside from the number of accessories on view, it was noticeable that several of the exhibits previously seen at the national shows in New York and Chicago were presented in their entirety. It is estimated that the value of the display was very close to \$1,000,000. Among the makes of cars on view were the following:

Pleasure cars—Marmon, National, Krit, Reo, Velle, Briscoe, Hudson, Jeffery, Studebaker, Hupmobile, Abbott-Detroit, Maxwell, Regal, Pathfinder, Havers, Pierce-Arrow, S. G. V., Simplex, Oakland, Haynes, Buick, Chalmers, Saxon, Kline-Kar, Winton, Cole, Stevens-Duryea, Cadillac, Peerless, Overland, Willys-Knight, Oldsmobile, Grant, Pullman, Mitchell and Paige. Cyclecars—Imp, Mercury, LaVigne, Rocket, Packet and Economy. Commercial vehicles—Buick, Walter, Morton, Peerless, Willys Utility, Adams, Velle, Pierce-Arrow, Koehler, Selden, Reo, Stewart and Garford.

NEW PLAN IN INDIANAPOLIS.

Dealers Hold Special Opening Week in Their Salesrooms Instead of Annual Show.

It probably was not due in any way to the fact that the worst flood in the history of Indianapolis took place last year during the progress of the annual show of the local dealers, but a new plan was tried this year and the results were so satisfactory in every way that it is possible that it will become an annual affair even though the show is renewed.

Beginning Feb. 21, each concern engaged in handling cars and accessories, inaugurated a special opening week, during which the salesrooms were decorated and the products arranged so as to call particular attention to their merits. Forty dealers, representing 55 different makes of cars in 180 models, took part in the event, which was a decided success from every viewpoint.

BIG RESULTS IN ST. LOUIS.

Spring Show Nets Dealers Taking Part Some \$500,000 in Sales of Cars.

Although a large number of the dealers in St. Louis, Mo., held an outdoor show last fall, conducted by the St. Louis Automobile Dealers' & Manufacturers' Association, the ninth annual spring exhibition in that city, which came to an end Feb. 26, was a decided success. Manager Frank Bishop reports that the dealers represented secured sales aggregating \$500,000.

Each of the exhibitors taking part was barred from the fall display. The spring show is to be conducted as in the past, but a movement is now on foot to hold a fall show in opposition to that conducted by the other body.

INSURANCE COST REDUCED.

Premiums Are 15 Per Cent. Less When Car Is Equipped with Pyrene Extinguisher.

Attention is again called to the recent action of several insurance companies in reducing the premiums on automobiles 15 per cent. where such cars are equipped with an approved fire extinguisher. This action is said to have been brought about through the efforts of the Pyrene Manufacturing Company, New York City, with branches in a number of cities, which markets the Pyrene fire extinguisher, shown herewith.

This extinguisher is of one quart capacity, 14 inches in length, three inches in diameter, and weighs but five pounds when filled and ready for use. It is said to be the only one of this capacity bearing the label of the Underwriters' Laboratories, Inc.

It comprises a cylindrical drawn brass tube, in which is a double acting, hand operated pump, designed to throw a stream of liquid at least 30 feet. The liquid is a compound of gases held to be devoid of moisture, acid, alkalis or salts, which, when thrown into a fire, is converted into a heavy, blanketing fire extinguishing gas.

It is maintained that the extinguisher preferably should be carried in a vertical position in a special vehicle bracket supplied for this purpose, on the dash or on one of the front doors. It is also stated that the compound will not freeze, even at temperatures as low as 60 degrees below zero, and that the container does not need to be recharged, except after actually having been used on a fire.

The Pyrene will be demonstrated at the forthcoming Boston show.

USED MILLER TIRES.

This Make Fitted to Joerman's Touraine, Fourth Place Car in Vanderbilt Race.

In addition to the accessories mentioned elsewhere as figuring prominently in the ninth race for the Vanderbilt Cup at Santa Monica, Cal., it is of interest to note that the tires used on Joerman's Touraine, which finished in fourth place, were of the Miller make, the product of the Miller Rubber Company, Akron, O. Miller tires hold the world's road racing record of 78.5 miles an hour, made over this course.

OMAHA SHOW OPENS.

Good Representation of Pleasure and Commercial Cars at Ninth Annual Display.

The ninth annual show of the Omaha Automobile Show Association was opened in the Auditorium, Omaha, Neb., under the management of Clarke G. Powell, secretary of the association, Feb. 23, for the entire week. The representation this year is much larger than heretofore, and included among the exhibits are a number of commercial vehicles. The success which has attended past efforts under the management of Mr. Powell, and the attendance during the opening days of the exhibition would seem to indicate a splendid season for the Omaha dealers. The list of exhibitors includes the following:

Pleasure Cars—Auburn Auto Company, Auburn; Apperson Jack Rabbit Auto Company, Apperson; Motor Car Sales Company, Abbott-Detroit; Nebraska-Buick Auto Company, Buick; Drummond Motor Company, Cole, Winston, Woods electric; Cadillac Company of Omaha, Cadillac; Cartercar-Nebraska Company, Cartercar, Metz; Doty & Hathaway, Chevrolet, Reo; Stewart-Toozzer Motor Company, Chalmers, Pierce-Arrow; W. L. Huffman Auto Company, Chandler, Hupmobile; T. G. Northwall Company, Detroit, Regal; Andrew Murphy & Son, Detroit electric; Empire Auto Company, Empire; Ford Motor Company, Ford; T. H. Pollock, Henderson; Guy L. Smith, Hudson; Inter-State Auto Company, Inter-State; Bradley, Merriam & Smith, Imperial; Rambler Motor Company, Jeffery; Pioneer Implement Company, Jackson, Richmond; Oppen-Van Fleet Auto Company, Kissel-Kar, Krit; Drummond Motor Company, Locomobile; Mitchell Motor Company, Mitchell, Lozier; Maxwell Motor Sales Corporation, Maxwell; Moline Auto Company, Moline-Knight; Marlon Auto Company, Marlon, Marmon; Traynor Auto Company, National, Partin-Palmer; Van Brunt Auto Company, Overland, Ohio electric; Lininger Implement Company, Oakland; Orr Motor Sales Company, Packard; Paige Company of Nebraska, Paige; Electric Garage Company, Rauch & Lang electric; E. R. Wilson Auto Company, Studebaker; R. N. Howes & Co., Stevens-Duryea; Freeland Auto Company, Spaulding; Wm. Pfeiffer, Speedwell; John Deere Plow Company, Velle; H. Pelton, White.

Commercial Vehicles—Avery Company, Avery; Nebraska Buick Auto Company, Buick; International Harvester Company, I. H. C.; Andrew Murphy & Son, Kelly; Orr Motor Sales Company, Packard; E. R. Wilson Auto Company, Studebaker; Wm. Pfeiffer, Speedwell; H. Pelton, White; Van Brunt Auto Company, Willys Utility.

Clarke G. Powell, Manager, Omaha Automobile Show.

MAGNETO CARE AND ATTENTION.

The Work Necessary to Maintenance, Continued Service and Efficiency Described and Illustrated---Directions for Timing and Installations on 1914 Cars.

(By C. P. Shattuck.)

WITH the manufacturer enlarging upon the refinements and equipment of his 1914 model, the ignition system is generally overlooked by the prospective purchaser, and this is but natural, as the reliability of the magneto has been conceded for some years past. Improvements, however, are noted, these including en-

Briggs Model C Magneto.

closed construction, preventing the entrance of moisture and foreign elements; the production of a hotter spark at low rotational speeds, and quicker acting interrupter mechanism. These features make for increased efficiency, and obviously the magneto requires less attention than formerly.

A review of the 1914 ignition systems reveals marked tendency toward single ignition, due to the general adoption of the motor starter, which relieves the owner of cranking and the necessity of auxiliary or battery

Simms S U W Six Magneto.

classified under two general heads, low-tension and high-tension. The armature of the latter carries a primary and a secondary winding and no induction coil is required as is the case with the low-tension instrument, but with some types of true high-tension magnetos, a second or independent breaker mechanism is incorporated to interrupt the battery

The Men Magneto, Type B H 4, Employing Bell Shaped Magnets.

current as with the Bosch, Eisemann and Simms for example.

The maximum efficiency or hottest spark is obtained from a magneto when its armature is in a certain position or when the greatest number of lines of magnetic force are cut, and as the primary current must be interrupted to induce a high-tension current in the secondary winding, it will be seen

that the time of breaking of the low-tension current is a most important factor. This breaking of the low-tension current is accomplished by the interrupter mechanism, which is generally attached to and revolves with the armature shaft.

New owners are sometimes advised to leave the magneto alone, and consequently regard it as

Eisemann E M Dual Magneto with Exterior Components Lettered.

ignition for starting. Dual ignition (magneto and battery) is, however, to be found on many 1914 cars, and it is the exception rather than the rule that two sets of spark plugs are used. Magnetos are

Model P Remy Magneto.

a delicate mechanism requiring the services of an expert to clean and adjust. While it is not probable that it will need frequent attention, the writer advocates an inspection of the interrupter mechanism from time to time, for after continued service it may be that the gap between the contact points has increased, affecting the efficiency of the motor.

There are three things the owners can do to obtain maximum efficiency from the magneto. These are: Clean, adjust and lubricate, and the work should be done according to the instructions of the maker. Provision is made for maintaining the proper gap between the contact points, an adjustable screw permitting of decreasing the space caused by wear, etc. Each maker supplies a wrench with gauge attached for determining the space between the points, and the operation of setting is easily performed.

Particular attention is called to the illustrations at Figs. 13 to 15 inclusive, as these not only show the interrupter mechanism, but depict its operation. Figs. 16, 17, 20 and 21 show the method of using a wrench and making adjustments, while Figs. 18 and 28 illustrate the use of the gauge. These and other illustrations show the progressive steps of removing, adjusting and cleaning the magneto, and as each step is explained the novice should, with a little study, be able to care for the magneto.

In timing or setting the magneto the exact location of the piston for the firing position is determined by the engineers of the maker of the car, and there are two methods, one by the position of the piston and the other by the flywheel or crank circle. With four-cylinder, four-cycle

motors the shaft rotating the magneto armature is driven at crankshaft speed and at one one-half times crankshaft speed with six-cylinder

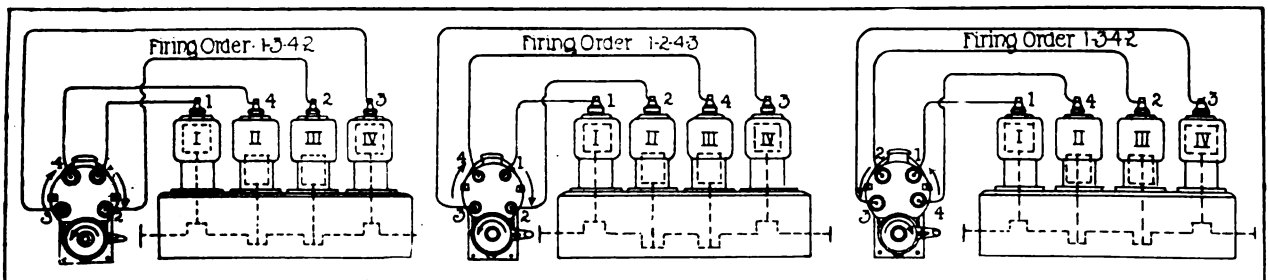

Timing Diagrams, Showing Positions of Crank and Piston for Magneto Setting: A, Piston 1/2 Inch Before Top Dead Centre, Corresponding to 33 Degrees Crank Circle; B, Piston at Top Dead Centre, or Completion of Compression Stroke; C, Location of Piston with Spark Lever Fully Advanced and Retarded for Battery, Commutator and Coil Ignition.

units. In connecting the driving member to the armature shaft in the event the magneto has been displaced from its base, for example, the coupling is made so that the break and spark will take place as determined by the designer of the motor.

With magnetos having timing windows or indicators, the setting is simplified. With the Bosch ZR4 and ZR6, for example, the armature shaft is rotated in its proper direction until the figure "1" is discernible through the timing window, and further revolved until the marked distributor tooth registers with marks on the side of the sight hole exposed by lifting the cover to the oil well. Several makers incorporate the timing indicator in their product. When not used the magneto will have to be set by the break of the points.

Previous to setting the magneto the time of spark in the first cylinder must be determined. It varies according to the design of the motor,

Wiring Diagrams of Four-Cylinder Magnetos: At Left, Magneto Running Clockwise and Firing Sequence 1-3-4-2; Centre, Armature Rotating Clockwise and Firing Sequence 1-2-4-3; at Right, Magneto Running Anti-Clockwise and Firing Sequence 1-3-4-2—It Should Be Borne in Mind That the Rotation of the Distributor Is Opposite to That of the Armature Shaft.

Fig. 1—Bosch ZR4: The Distributor Plate Is Retained by Two Holding Springs—Push Outward.

Fig. 2—Holding Springs Displaced and Distributor Plate Ready to Be Removed from Magneto.

Fig. 3—Grasp Distributor Plate, Pull Directly Forward, Place Carefully to One Side for Inspection.

Fig. 4—The Interrupter Housing Is Held by a Snap Ring and Is Removed as Shown.

but as the setting and firing order of the 1914 models are given herein it should be a simple matter. It will be noted that there are three general piston locations given: Before top dead centre, dead centre and past dead centre. Centre is referred to as the completion of the compression stroke, and as the majority of flywheels are marked, the work is simplified. An accompanying timing diagram shows the location of the piston both by its travel in inches and degrees of the crank circle.

It will also be seen that reference is made to the position of the magneto timing lever, and in some instances it is fully advanced and in others fully retarded. These points may be determined easily by noting the direction of rotation of the armature shaft and break of the points, or operating the hand spark lever. For example: Fig. 4 shows a magneto driven clockwise (looking at the driving end) and the timing lever fully retarded. Fig. 1 depicts the lever fully advanced,

thereby causing an earlier break of the contact points. Relative to the "points just beginning to break", Fig. 14 shows the contact block touching the segment and the points separating.

If for any reason the secondary cables are displaced, a knowledge of the firing order of the motor and the direction of rotation of the distributor gear of the magneto will be necessary. If it is borne in mind that the distributor rotates in a direction opposite to that of the armature shaft, and that the cables are connected according to the firing order of the cylinders, no trouble should be experienced. Accompanying wiring diagrams show how to properly connect the secondary cables with four and six-cylinder magnetos and the various firing sequences are also given.

The writer is indebted to the engineering departments of the manufacturing concerns producing 1914 models listed herein for the data on magneto timing and the firing order of the motors presented in detail in the succeeding pages:

TO HANDLE ADVERTISING.**Bruce Daniels Leaves Pathfinder Concern to Go with Stutz Company.**

Announcement is made by the Stutz Motor Car Company, Indianapolis, Ind., that Bruce Daniels will handle Stutz advertising in the future, as well as act as assistant to Sales Manager W. D. Myers. The latter is planning to spend much of his time on the road during the period preceding the holding of the 500-mile race on the Indianapolis speedway, May 30.

Daniels was for two years advertising manager of the Motor Car Manufacturing Company, maker of the Pathfinder, another Indianapolis concern. According to Myers, the increasing business of the Stutz company and the continued success of Stutz racing cars have made it necessary to establish the department which Daniels now heads, in order to handle more efficiently the advertising and detail work of the sales department.

LEXINGTON-HOWARD COMPANY.**Organized to Take Over Production of Two Well Known Makes of Cars.**

Announcement was made a short time ago of the organization of the Lexington-Howard Company of Connersville, Ind., which has purchased the good will and trade names of the Lexington

Motor Car Company, incorporated in 1908, and the Howard Motor Car Company, which came into existence about the time of the 1913 Chicago show, the direct successor of the Central Car Company. The new concern will continue the production of Lexington and Howard cars, under a combined management, which is expected to result in obvious benefit to purchasers of these machines.

The Lexington is a four-cylinder car and the Howard a six. The statement recently made public by the company sets forth that they are two distinct lines, built in two distinct factories, reaching two distinct fields, but with only one overhead cost. The policy of the company is still further explained in the following signed announcement from E. W. Austel, president:

Why should the automobile business be different from any other business? To my mind it is not, and the sooner it gets down to a horse sense basis the healthier it will be. The day when it was a "game" is gone. The red fire and hurrah period is past. And the companies which stay in are the ones which are going to adopt a hard headed, close margined, businesslike policy.

Correction of Error—In the Jan. 25 issue of The Automobile Journal, the statement that the B. F. Goodrich Company, Akron, O., had reduced the tire mileage guarantee on certain solid tires made by it was in error, insofar as it was made to appear that electric vehicle tires were included in the reduction from 8000 to 7000 miles. The Goodrich company explains that the guarantee for tires on electric vehicles is 8000 miles if run out in 18 months.

ACCO LUBRICANTS.

Composed of Mineral Compounds and Held to Be Free from Acids.

The A. C. C. Oil Company, Boston, is marketing Acco, which is held not to be a grease, but a lubricant composed of mineral compounds scientifically blended, free from mineral or animal acids and corrosive action. It may be termed a universal lubricant, in that it is used for everything requiring lubricating, from the largest to the smallest gear, and all components of the automobile, motor truck or motorcycle, except the motor.

The company calls particular attention to the adhesive-cohesive qualities of Acco, stating that it follows the gears and is not thrown off by centrifugal force. It is also claimed that it does not channel and has a very high fire test, the minimum flash point being about 600 degrees Fahrenheit. It is pointed out that Acco forms a film around the balls and rollers of bearings and positively lubricates them, no matter at what angularity they may be.

Because of its adhesive qualities it is stated that less is needed to lubricate properly, making for economy. Another claim made for Acco is that it quiets metallic sounds and gear noises and is not affected by high temperatures or pressure. The maker states it can be removed easily from any metal or surface by paper or cloth, as no solvent is needed to displace it. Acco is put up in five, 10, 25 and 50-pound packages and comes in glass jars, in tins and in half-barrels and barrels.

CONTEST BOARD MEETING.

Accepts Dirt Track Records and Takes Action on Cyclecar Matters.

At a meeting of the contest board of the American Automobile Association held in New York City, Feb. 11, it was voted to accept the following circular dirt track records, sufficient proof having been submitted to the board: Fifty miles, Disbrow, Simplex, 40:32, Detroit, Sept. 29, 1912; 200 miles, Mulford, Mason special, 3:21:48, Columbus, O., July 4, 1913.

Following a resolution adopted at the annual meeting of the association at Richmond Va., in December, the board went on record as being in favor of embracing, in the 1914 contest rules, classifications and regulations governing cyclecars, and manufacturers of cyclecars were invited to make suggestions along these lines. A

communication was received from Secretary Stout of the Cyclecar Manufacturers' National Association, and the board replied that it was its desire to co-operate to the fullest extent with that body, and invited it to name a representative on the board.

GENEVA'S AUTOMOBILE SHOW.

Twenty-Four Makes of Cars Represented in Third Annual Dealers' Display.

The third annual motor vehicle show of the Geneva Automobile Dealers was held in state armory, Geneva, N. Y., Feb. 11-14, under the management of Louis Blumenstein. Twenty dealers exhibited 24 makes of cars, amid surroundings which served to call special attention to the merits of the vehicles on exhibition. The show was in every way a success, and served as an excellent stimulant to business.

The makes of cars shown were the following: Pierce-Arrow, Chevrolet, Buick, Maxwell, Hudson, Studebaker, Overland, Wahl, Cole, Franklin, Reo, Lyons-Knight, Ford, Mitchell, Lozier, Chandler, Paige, Regal, Cadillac, Saxon, Haynes, Premier, Geneva delivery wagon and Willys Utility wagon.

BLOOMINGTON'S FOURTH DISPLAY.

As a Result Local Dealers Expect to Exceed Business Done Last Year.

During 1913 the 20 dealers in Bloomington, Ill., of which four carry trucks and three electric vehicles, sold 800 cars. There are also 12 garages and three supply houses in the city, all of which are members of the recently organized Bloomington Dealers' & Garage Proprietors' Association. However, the McLean County Automobile Club conducted the fourth annual show Feb. 18-21, as in the past.

The attendance, as well as the business transacted, at the exhibition just ended was such as to place the dealers and others in a very optimistic frame of mind, and it is freely predicted that the number of sales for 1914 will greatly exceed those for 1913. The show was held in the Deere building, under the management of C. C. Wagner. The following made display:

C. C. Davis, Davis; Floyd Iseninger, Ford; J. M. Ijams, Mitchell; F. H. Cole, Hudson; Trott & Stubblefield, Stutz, Marion, Herff-Brooks; D. H. Cornell, Ohio electric; T. K. Hays, Cadillac, Buick; C. U. Williams & Son, Chalmers, Overland, Saxon, Woods electric; J. L. Murray & Co., National, Reo; Ingram Motor Car Co., Jeffery; Gus Shrolle, Allen; Chester Marquis, Marmon, Hupmobile, Detroit

electric; R. E. Herr, Partin-Palmer; T. E. Stewart, Oakland; F. F. Sweeting, American; Patton & Son, Moon; Martin & Clark, Maxwell; Jacob Razor, Lozier, Paige; Laura J. Dooley, Imperial.

MORE ROOM AT KANSAS CITY.

Management Finds It Necessary to Provide for 33 Additional Exhibitors.

Although the annual automobile show in Kansas City is held under the direction of the Kansas City Motor Car Dealers' Association, and no space is sold except to members of that organization, it was found necessary this year to provide additional space by the construction of a temporary balcony, containing 33 spaces. The display was made in Convention hall, and was, in effect, a district show, some 1200 dealers in the Southwest taking advantage of the opportunity afforded for examining the season's offerings. The manager was E. E. Peake, secretary and treasurer of the association, and the list of exhibitors included the following:

Gasoline Pleasure Cars—Auburn Auto Company, Auburn; Bond Motor Company, Maxwell; Bruening Bros. Auto Company, Apperson; Cartercar Company, Cartercar; Chalmers Motor Company, Chalmers; J. I. Case Threshing Machine Company, Case; Cole Motor Company, Cole; Dey-Embry Motor Company, Pierce-Arrow; Franklin Motor Company, Franklin; Ford Motor Company, Ford; Greenlease Motor Company, Cadillac; Hall Bros. & Reeves, Premier; Paige; Holcker-Elberg Manufacturing Company, Peerless; Hupmobile Sales Company, Hupmobile; Hudson-Latham Motor Company, Hudson; Imperial Motor Company, Imperial; Jackson Motor Company, Jackson; Karshner Motor Company, Speedwell, Stutz; KisselKar Branch, KisselKar; Locomobile Company of America, Locomobile; Mitchell Motor Company, Mitchell; Motor Sales & Service Company, Krit; Moriarity Motor Company, Lozier, Abbott-Detroit, Regal; Missouri & Kansas Auto & Supply Company, King; Nordyke & Marmon Company, Marmon; Oakland Motor Company, Oakland; Overland Company, Overland; Oldsmobile Company of Missouri, Oldsmobile; Packard Kansas City Company, Packard; W. A. Paterson Motor Company, Paterson; Rambler Distributing Company, Jeffery; Stafford Motor Company, Stafford; Southwest Motor Company, Reo, Chevrolet; Studebaker Corporation, Studebaker; Velle Motor Company, Velle; Winton Motor Company, Winton; Western Motor Company, Pathfinder, Empire.

Electric Pleasure Cars—Anderson Electric Car Company, Detroit; Baker Electric Company, Baker; Bruening Bros. Auto Company, Waverley; Dodge-Robinson Motor Company, Woods; Ohio Electric Vehicle Company, Ohio; Rauch & Lang Company, Rauch & Lang.

Steam Pleasure Cars—Stanley Steamer Agency, Stanley.

Commercial Cars—Buick Motor Company, Buick; General Motors Truck Company, GMC; Holcker-Elberg Manufacturing Company, Federal; International Motor Company, Saurer; Kelly-Springfield Truck Company, Kelly; KisselKar Branch, KisselKar; Overland Company, Willys Utility; Packard Kansas City Company, Packard; Velle Motor Company, Velle; White Motors Company, White; H. E. Wilcox Motor Car Company, Wilcox.

The Stafford is made in Kansas City and the company has planned for an output of at least 125 cars during the coming season.

MOLINE-KNIGHT ORDERS.

President Van Dervoort Says Recent Test Has Increased Demand for Cars.

At no time during its 10 years of existence, according to President W. H. Van Dervoort of the Moline Automobile Company, East Moline, Ill., has that concern received so many orders for cars as during the past few weeks. He believes much of this increase in business to be due to the international records for power, endurance and economy established by the Moline-Knight motor in the recent test in the laboratory of the Automobile Club of America. He says:

The test, however, is not the only reason why extra help has been employed, why new automatic machinery is being installed, and why dealers from the Atlantic to the

Convention Hall, Scene of Successful Kansas City Automobile Show.

Pacific are contracting for Moline-Knights. Other reasons which have caused the Moline-Knight stampede are due to the facts that it is the lowest priced Knight motor car ever offered the public, only Knight with thermo-syphon cooling, only Knight in America with cylinders cast en bloc, and because of its unusual body lines and large dimensions, superior upholstery and finish and the unusually complete equipment.

The Oakland Motor Car Company, Pontiac, Mich., reports that a carload of Oakland cars left the factory this month consigned to Lininger Implement Company, Omaha, Neb., and a second will be shipped in March. An order also has been received from G. W. Hanson of the Oakland Motor Sales Company in Atlanta, Ga., for 10 carloads, and he states that he expects to increase this by the addition of another carload in the near future. These orders, together with those received as the result of recent shows, will tax the shipping department to its fullest capacity.

GENERAL NEWS OF THE INDUSTRY.

Price of Gasoline Is Reduced One Cent a Gallon---Another Model of Thomas Car Is Announced---Knox Plant to Be Sold---New Concerns Organized.

FEBRUARY 24 the price of gasoline was reduced one cent, from 17 to 16 cents a gallon, in 50-gallon lots or more. Probably nothing could cause more interest among motorists generally than this announcement. It means much to the industry as a whole, although several more reductions will be necessary before the price of gasoline reaches a point coincident with that prevailing at the close of 1912.

Soon after Jan. 1, 1913, the price of gasoline was increased from 50 to 80 per cent., depending upon the section of the country. At that time it was explained that several contracts had been in force for some time, and that really the price had been advancing during the life of these contracts, so that the full force of these cumulative advances was felt at one time.

Immediately thereafter, steps were taken, both in this country and abroad, to secure a satisfactory substitute for gasoline, and the resulting experiments and investigations have been continued since that time. It is not expected that announcement of a reduction in price will have any appreciable effect upon this situation, at least at present.

No reason is assigned for the action taken Feb. 24, and those by whom the announcement was made state that they are not in a position to offer any suggestions as to probable future reductions.

ISSUES GOLD BONDS.

Maker of Case Cars Arranges This Plan to Reduce Its Current Loans.

Announcement is made from Racine, Wis., that the J. I. Case Threshing Machine Company of that city, maker of Case cars, has sold to a syndicate, composed of the First Trust & Savings Bank of Chicago and Potter, Choate & Prentice of New York City, an issue of \$12,000,000 first mortgage, six per cent., serial gold bonds, maturing at the rate of \$1,000,000 annually from Dec. 1, 1914, to Dec. 1, 1926. It is understood that this action was taken in order to reduce current loans.

According to a published statement by President F. K. Bull, the profits of the Case company are largely in excess of the amount required to

pay the interest on these bonds and the dividends on the preferred stock. Its quick assets will, according to this same authority, equal the entire amount of obligations, including the bonds now issued, and also the entire par value of the preferred stock outstanding.

The company has an authorized capitalization of \$20,000,000 each of preferred and common, there being at present \$12,150,000 of the former and \$8,300,000 of the latter outstanding.

NEW THOMAS CAR.

E. R. Thomas Motor Car Company of Buffalo Announces Six-Cylinder Model.

Although nothing has been heard from the E. R. Thomas Motor Car Company, Buffalo, N. Y., for some time, a dispatch from that city contains the information that it has brought out a new model Thomas car for the 1914 season. This is to be known as model MCX, and will be built in limited quantities.

It is understood that the motor is a six-cylinder unit, cast in pairs, with bore of 4.25 inches and stroke of 5.5. Ignition is to be by Bosch high-tension magneto and Atwater Kent Unisparker with battery. The chassis is to be the same as the 1912 MC, with wheelbase of 134 inches. Wire wheels and a Gray & Davis lighting and starting system are to be included in the equipment. Five and seven-passenger touring bodies are to be fitted.

TO SELL KNOX PROPERTY.

Court Orders Disposition Either at Private Sale or Auction.

According to an announcement made by Charles G. Gardner, trustee of the Knox Automobile Company of Springfield, Mass., the entire property of the concern will soon be sold either at a private sale or at auction. The company has been operating under bankruptcy for over a year, the receivership dating from Jan. 21, 1913.

The announced sale will include the factory, machinery, fixtures, supplies, parts and cars finished and in the process of construction. Offers

for the whole or any part of the real estate or personal property will be considered and the buyer of the plant acquires the good will of the company and the use of the Knox name.

The trustee states that during the period of bankruptcy the concern has done a gross business of \$1,250,242.21, and, considering the handicap of operating under the direction of the court, this showing would seem to be a most favorable one. It is also stated that during the past few weeks there has been a very gratifying increase in the number of orders received and that the outlook for future business is very encouraging.

The trustee's statement, dated Nov. 30, 1913, shows the following assets:

Real estate	\$298,012.49
Machinery and equipment	224,874.83
Agency equipment	5,000.00
Patterns and drawings	36,936.46
Merchandise inventory	859,337.78
Unexpired insurance	8,000.00
Accounts receivable, net	186,586.65
Cash	15,666.68
Total	\$1,634,414.89

HERRESHOFF LIGHT CAR.

New Product to Be Manufactured in Troy, N. Y.—Will Be Displayed at Boston.

Announcement is made by the Herreshoff Motor Sales Company, Troy, N. Y., of a Herreshoff light car, which will be produced in that city. The product will be displayed for the first time at the forthcoming Boston show. It seats two passengers side by side, and has a wheelbase of 90 inches, tread of 44 inches and weight of 750 pounds.

The motor is a four-cylinder, L head unit, cast en bloc, with bore of 2.375 inches and stroke of 3.75, being rated by the maker at 16 horsepower. Ignition is by the Atwater Kent system. Cooling is by thermo-syphon. Power is transmitted by a cone clutch, three-speed selective gearset and shaft. Quarter-elliptic springs are used.

TO MAKE ALTER CAR.

Detroit Concern Purchases Land for a Factory Site in Plymouth, Mich.

The Alter Motor Car Company has been organized in Detroit for the purpose of producing the Alter car, with 106-inch wheelbase, standard tread and a five-passenger body. The officers are: President, Guy Hamilton; vice president, C. A. Alter; secretary and general manager, R.

A. Skinner, and treasurer, R. S. Todd.

The main offices of the concern are to be located in Detroit, but it is understood that 26 acres have been purchased in Plymouth, Mich., on which to erect a factory.

FORMS NEW COMPANY.

Leslie S. Hackney Organizes Concern to Manufacture Roller Bearing Accelerator.

Leslie S. Hackney of St. Paul, Minn., has perfected a simple, compact roller bearing accelerator, and has formed the Roller Bearing Foot Pedal Company, of which he is president and owner. The concern will have general offices in the Hackney building.

Mr. Hackney has invented a number of mechanical devices and his name is familiar in agricultural circles as the manufacturer of the Hackney auto plow and light farm tractors. He is also the inventor and manufacturer of the Hackney system of ventilation, a cooling

Leslie S. Hackney, Inventor of Roller Bearing Accelerator.

system for internal combustion engines, and numerous other labor saving devices.

BRETZ TAKES CONTROL.

Secures Principal Interest in Massnick-Phipps Manufacturing Company.

The J. S. Bretz Company, New York City, has purchased the controlling interest in the Massnick-Phipps Manufacturing Company, Detroit, according to announcement made in that city. The latter concern does contract machine work, principally the manufacture of motor car parts, and at present is interested in the development of a cyclecar motor. It also makes the La-Vigne steering gear.

LEAVES CATARACT RUBBER.

Richards Interest in That Concern Taken Over by Providence Banking House.

Announcement is made of the resignation of Stephen J. Richards, as director and general manager of the Cataract Rubber Company, Boston, Mass., with factory in Wooster, O. He also was the owner of a large interest in the company, which has been taken over by Newton P. Hutchinson & Co., an investment banking house in Providence, R. I.

During his connection with the company, Mr. Richards worked exceedingly hard to build up the business and place the product on a par with the quality tires of the country, and was decidedly successful in that respect. In accepting his resignation the board of directors was moved to pass the following resolution:

We hereby accept the said resignation of Mr. Stephen J. Richards as a director and the general manager of this company, and in accepting same we wish to recognize his efforts in building up the business of the company and the further fact that it is very largely through the efficient work done by him that the company has reached its present condition in the rubber tire business.

BUYS INTER-STATE PLANT.

New Concern Is Organized in Muncie, Ind., to Continue Production of Cars.

At the auction sale of the Inter-State Automobile Company's plant in Muncie, Ind., early in the month, the entire property was purchased by Frank C. Ball for \$215,000. Immediately thereafter the Inter-State Motor Company was organized with the following directors: George A. Ball, E. B. Ball, Frank C. Ball, J. M. Maring, Theodore F. Rose, F. D. Rose and B. W. Twyman. This concern has taken over the property and will continue the manufacture of Inter-State cars, and it is also understood that plans are under way for the production of a new model to sell at a popular price.

The Ball brothers have long been engaged in the manufacture of Mason fruit jars, and are interested in factories in Muncie, and Wichita Falls, Tex., and in street car lines throughout the country. Mr. Maring is identified with manufacturing interests in Muncie, New Castle and Terre Haute, Ind.; Danville, Ill., and Mansfield, O., and is best known from his connection with the production of the Hoosier kitchen cabinet. Theodore F. Rose is president and F. D. Rose, cashier, of the Union National Bank.

Mr. Twyman, who has assumed the position

of general manager in charge of production and sales, has had long, successful experience with bicycles and automobiles. During the early '90's he was a bicycle racing rider, and was for a long time actively connected with the Black Manufacturing Company, Erie, Penn., until the sale of that concern to the American Bicycle Company. Later, he went with the Waltham Manufacturing Company, Waltham, Mass., maker of Orient wheels, and followed that concern into the manufacture of automobiles. His next experience was with the Logan Construction Company, Chillicothe, O., and then with a number of jobbing concerns in automobiles and accessories in Indianapolis. He next became sales manager of the E-M-F Company, and, subsequently, of the Studebaker Corporation, both of Detroit. More recently he has been engaged as president of the Twyman Motor Car Company, Columbus, Cincinnati and Dayton, O., one of the biggest automobile jobbers in this country.

PURCHASE HAGSTROM FACTORY.

Sales Office Will Be Located at Salina, Kan., and Plant at Linsborg.

Announcement is made from Salina, Kan., that the plant of the Hagstrom Manufacturing Company, located at Linsborg, Kan., has been purchased by a company composed of the following: President, J. F. Merrill, president of the Farmers National Bank of Salina and of the Falun State Bank; production manager, Charles Lander, a member of the state legislature and the board of regents, and sales manager, R. J. Laubengayer, who has been connected with the sales departments of various eastern manufacturing concerns.

The new company is understood to be well supplied with experience and financial backing, and will continue to produce the well known Hagstrom electrical, rubber and hardware specialties. The line of blow-out patches will be augmented by the addition of a new patch, to be known as the Hagstrom Swede, which will sell at a popular price. The sales office will be retained at Salina.

The Bosch Magneto Company, New York City, reports that the 1914 models of the following makes of motorcycles are equipped with Bosch ignition: Dayton, DeLuxe, Eagle, Excelsior, Flying Merkel, Harley-Davidson, Iver Johnson, Jefferson, Michaelson, Minneapolis, Pope, R-S, Thor and Yale.

SUGGESTIONS FOR THE NEW CAR OWNER.

IF ONE desires to obtain maximum efficiency from motor, care should be taken to occasionally verify the clearance between the valve

Model 79 Overland Valve Tappet Mechanism.

stems and the plungers of the valve mechanism. This may be accomplished by one of two methods, either by inserting an ordinary visiting card between the valve stem and the tappet, or by checking the opening by utilizing the marks

on the flywheel. An accompanying illustration shows the components of the valve mechanism of the model 79 Overland, and it will be noted that means are provided for increasing or decreasing the clearance between the plunger and the valve stem by loosening the locking nut and rotating the adjusting nut. Rotating the nut to the right increases the clearance, to the left decreases the space.

In adjusting for wear, etc., care must be taken to note that the valve is seated, and it is suggested that each valve be adjusted separately.

While the use of a card is suggested by the maker of the car, better results will be obtained if the flywheel markings are utilized. The periphery of the flywheel is marked 1-4 I-C, which indicates the opening point of the intake valves of the first and fourth cylinder. (The No. 1 is the cylinder nearest the radiator.) Rotate the flywheel by hand, opening the compression cocks to lessen the compression, until the marks referred to register with the punched guide mark on the plunger and valve stem is correct, the intake valve of the first cylinder should begin to lift. If early or late, it should be corrected by the adjustment previously referred to. The opening and closing points of the exhaust valves are determined by the flywheel markings, which are indicated by the letters E-O and E-C.

BUICK CLUTCH CONSTRUCTION.

The clutch used with models B 24 and B 25 Buick cars is of the leather faced cone type, hav-

ing three small springs to make for easy engagement. The components are shown in an accompanying sectional view, also the points requiring lubrication. These are the clutch spindle, lubricated by a grease cup, and a pipe plug for lubricating the sleeve and thrust bearing. The only adjustment of the clutch mechanism is the pedal, which releases the clutch cone from the flywheel.

The clutch cone is tapered and a large, heavy coil spring, enclosed in a sleeve, tends to force it into contact or engagement with the flywheel member. At the rear of the sleeve is a coupling which connects the clutch with the clutch shaft of the gearset. The sleeve carries a collar so retained and connected with the clutch pedal that when the last named member is depressed the coil spring is contracted. Or in other words, the cone is disengaged from contact with the flywheel member. When the spring is compressed, the clutch, after overcoming the inertia imparted by the flywheel, remains stationary, riding on the clutch spindle. This permits of interrupting the transmission of the motor's energy to the gearset and road wheels, as when stopping the car or starting the motor for example.

Oil or grease should not be placed in the clutch housing, as the use of a lubricant will cause the clutch to slip. If the leather becomes hard or dry, it may be softened by the appli-

Sectional View of Clutch Used with Models B 24 and B 25 Buick, Showing Method of Assembly.

cation of a few drops of neatsfoot oil. Should the facing become oily, the maker recommends the use of very fine fuller's earth.

WITH THE MOTORING INTERESTS ABROAD.

Public Sentiment on Prince Edward Island Presages Increased Market for Cars in the Near Future--Hornsted Exceeds One American Record--Foreign News.

LAST year the provincial legislature on Prince Edward Island decided that automobiles could be operated with safety on the streets of the two principal cities, Charlottetown and Summerside, three days a week. The new regulations went into effect in July, and since that time 35 cars have been brought into the province. A movement is now on foot to permit operation six days a week and on a number of the principal highways extending through the province.

In the early days of the industry the few cars that made their appearance on Prince Edward Island frightened the horses, and immediately there arose a storm of protests from the rural sections. The regulations of 1913 were so worded as to prohibit the use of motor vehicles on market days, when the rural population was present in the cities in large numbers. It is stated, however, that public sentiment in these outlying districts is somewhat less intense, and that there is every probability that more extensive use of cars will not meet with decided opposition.

The Charlottetown Y. M. C. A. has opened an automobile school for intending chauffeurs and garage men, which now has 45 pupils. There is every indication that at the completion of the present term a sufficient number of new pupils will be secured to warrant a second class. An American instructor has been engaged and the course is to be very thorough. Sessions are held during the day and evening, and at the completion of the regular course, 10 lessons in operation are to be given separately.

Should the proposed legislation be enacted, which seems entirely probable, there will be an immediate demand for 50 or 75 automobiles and light delivery wagons, according to Consul Wesley Frost, located at Charlottetown. A list of possible agents may be procured by addressing the bureau of foreign and domestic commerce, Department of Commerce, Washington, D. C.

MORE HORNSTED RECORDS.

English Driver Succeeds in Lowering American Mark for Flying Half-Mile.

As stated in the Feb. 10 issue of The Automobile Journal, Hornsted of England has been busy with a 200 horsepower Benz on Brooklands

track, Weybridge, England, throughout the past month in an effort to create new world's records, under the plan recently adopted abroad. It would seem from the advices from Great Britain that none but marks established by taking the mean time for a run in both directions were to be accepted as world's records in the future. What becomes of the world's records already adopted by the American Automobile Association does not appear to enter into the consideration.

Hornsted has created new records under the above plan for the standing kilometer, half-mile and mile, and for the flying two, five and 10 miles. In each instance the time has been slower than that accepted by the American Automobile Association, but it must be remembered that there are no such classifications as standing kilometer, half-mile or mile in this country. The Hornsted marks for the above, with the exception of the standing mile and flying 10 miles, were presented in the last issue. His time for the mile was 41.21 (mean time), as against Burman's 25.40, made with the Blitzen Benz at Daytona, Fla., April 23, 1911, although Burman's mark was made from a flying start. Hornsted's time for 10 miles was 5:19.78, as against 5:14.40, made by the late Bruce-Brown in a Benz at Daytona, Fla., March 24, 1909.

However, Hornsted has driven a half-mile, from a flying start, in less time than that represented by the American record, made by Burman in the Blitzen Benz at Indianapolis, Ind., May 29, 1911. His time was 14.53, as against Burman's 16.80, but as it was made in one direction only, it is not credited as a world's record in Great Britain.

ELECTRICS IN TORONTO.

Many Machines of This Type in Constant Service Despite Climatic Conditions.

Because of the heavy snow fall in Canadian cities, those who are not familiar with the facts may be led to believe that it is difficult to operate motor vehicles successfully during the winter months. In Toronto, for instance, where the snow fall for the winter of 1910-11 was 61.3 inches, and for the winter of 1911-12, 76.4 inches, electric passenger and freight cars have been in use for a

number of years. During the past three years these have not been withdrawn from service save for short periods after severe blizzards.

The oldest user of electric vehicles in Toronto is the Verral Company, operating nine sight-seeing machines and a taxicab. Other users include: Robert Simpson Company, department store, five; Heintzman & Co., piano manufacturer, one; M. Langmuir Manufacturing Company, trunk maker, one; Holt-Renfrew Company, furrier, one; T. R. Estabrooks Company, tea importer, one; Bowles Lunch, Ltd., restaurateur, one; McClary Manufacturing Company, stove manufacturer, one; O'Keefe Brewing Company, four; Canadian Express Company, three; Toronto Electric Light Company, two, and Central Press Agency, one.

An accompanying illustration shows the five Detroit electric wagons used by the Robert Simpson Company's department store. Several others

three; Star, two; Vauxhall, three; Martini, one; Adler, three; D. F. F., one.

A. T. Hennessy, vice chairman of the Royal Automobile Club of South Africa, has sent samples of Natal coal to Great Britain for the purpose of determining its value as a producer of benzol, with the object, if found suitable, of establishing a benzol refinery in South Africa.

According to Consul-General Alban G. Snyder of Panama, there are about 120 cars, all gasoline, licensed in the Republic of Panama, of which 50 are for commercial use (hire in garages) and the remainder in private service. With the exception of two French machines, all are of American manufacture.

The newly organized Automobile Club di Sicilia is planning an automobile and motorcycle show to be held in Palermo, Italy, beginning April 21. Its special object is to encourage the use and promote the sale of motor vehicles in Sicily. All types of cars, motorcycles and accessories are to be admitted, and it is expressly desired that American manufacturers make entry. Applications must be addressed to the Automobile Club di Sicilia, Via Catania, No. 2, Palermo.

As a result of a new convention of European countries respecting the use of the international touring pass, a new rule is soon to be in force. Heretofore it has been necessary for the tourist to deposit with the organization of which he was a member sufficient money to cover the duty relating to the car in each country in which he de-

Five Detroit Electric Wagons in Service with the Robert Simpson Company's Department Store in Toronto, Can.

are Detroit machines, while the other makes represented are the G. V., Waverley, Riker, Commercial and the product of the Motor Car Equipment Company. Some of these machines are 10 years old.

NEWS NOTES FROM ABROAD.

At the invitation of the Imperial government of Germany the international road congress in 1916 will be held at Munich.

The value of the motor cars imported into Japan during the first nine months of 1913 was about \$450,000, as compared with \$290,000 for the same period in 1912.

At the recent Scottish automobile show in Edinburgh the following American machines were on display: Cadillac, Ford, Hupmobile, Maxwell, Oakland and Bedford-Buick.

The following cars have made entry for the 1914 Grand Prix of the Automobile Club de France, July 4: Alda, one; Peugeot, three; Sunbeam, three; Nazzaro, one; Opel, three; Mercedes, five; Caesar, one.

The following cars have been entered for the 1914 Tourist Trophy race on the Isle of Man in June: Minerva, three; Humber, three; Straker-Squire, two; Sunbeam,

sired to travel. The new rule will provide that the deposit shall be only that of the highest customs charge made in any of the countries in which he is to tour.

The Society of Manufacturers & Traders, in Great Britain, recently completed a postal ballot of its members on the subject of whether or not to hold a motor show in Manchester, England, next year, with the result that 220 voted in favor of the proposition and 413 against. The vote of the exhibitors was 49 for and 61 against.

Official reports from Nova Scotia state that the people of the province now have invested in automobiles some \$2,000,000. Most of these are of American manufacture, although there is an automobile manufacturing plant located at Amherst, which is reported to have a yearly production of about 60 cars. A recent reliability tour, covering approximately 500 miles, the first to be held in the province, has done much to awaken interest in improved highways, and it is expected that every effort will be made to induce tourists to visit Nova Scotia in 1914.

The Imperial Automobile Club of Germany has addressed a circular letter to the affiliated clubs in other countries asking for co-operative consideration of ways and means for securing uniform rules of the road. This circular points out that in England, Luxemburg, Portugal and Sweden, vehicles keep to the left and pass to the right, while in all other countries the opposite rule obtains, although in some European countries there are regions where the vehicles are expected to keep to the right in some instances and to the left in others.

NEW ACCESSORIES FOR THE MOTORIST.

K. P. FOOT REST HEATER.

Utilizes Exhaust to Warm Interior of the Automobile.

The K. P. Foot Rest Heater, manufactured by the K. P. Foot Rest Heater Company, 210 South 17th

street, Philadelphia, differs from the conventional types of heaters utilizing the exhaust, in that it may be used also as a foot rest. One of the qualities of the device is that the control valve is incorporated in it, convenient to the occupant of the tonneau.

The exhaust is conveyed by a flexible tubing, and after passing through the tube heater, passes to the muffler. It is stated that there is no noise or back pressure, as the gases travel through tubes of constantly increasing diameter. The heater comes in an oxidized, nickel plate or brass finish. When desired the foot rest bar can be covered with carpet to match that of the floor.

BRIGGS MAGLITE GENERATOR.

A Combination Dynamo and Ignition Equipment.

The Briggs Magneto Company, Elkhart, Ind., maker of ignition specialties, is manufacturing the Briggs Maglite, which is a combined lighting generator and ignition unit. It is designed to be mounted on the base provided for the magneto, and is driven through the pump or other convenient shaft, at crankshaft speed when utilized in connection with four-cycle, four-cylinder motors.

The Maglite generates a direct current for charging the storage battery and for lighting the lamps. Its lower half consists of an armature revolving in an electro-magnetic field to generate current, and the field has two windings. One of these is out of

circuit when the unit is operating without the lamps. This is held to avoid overcharging the cells.

The upper half of the instrument is employed for ignition. It consists of a circuit breaker, similar in principle and construction to those employed on conventional magnetos. It mechanically closes and opens the circuit in exact synchronism with the motor, and has a wide range of advance and retard. In addition to this, it has a magneto distributor which automatically distributes the high-tension current to the spark plugs and according to the firing order of the motor.

MOSCO ANTI-RATTLER.

Designed Especially for Ford Steering Gear and Radius Rods.

The Motor Specialties Company, Waltham, Mass., with New York office at 50 Church street, is manufacturing the Mosco anti-rattling ball sockets, which are practical devices for eliminating the rattle of the joints at the ends of the steering gear connecting rods and the ends of the radius rods on Ford cars. They are made in two sizes, the larger be-

ing utilized with the radius rods.

The Mosco automatically takes up play and without restricting the movement of the steering linkage, which invariably results when the two halves of the joint are filed to eliminate lost motion. Adjusting means are provided by a screw member which moves a cup shaped plunger, decreasing the movement of the ball member. The movement of the anti-rattler is obtained by the use of a rubber pad which not only maintains an even pressure on the ball member, but absorbs all road shocks. The Mosco anti-rattler is inexpensive.

EDITOR'S COMMENT.

The editor desires to call the attention of manufacturers, distributors and agents to the necessity of giving their street address when forwarding data for use in this department. Many complaints have been received from readers who state that their letters were either returned or no answer was obtained. The need of the complete address is obvious.

HANS TANK GAUGE.

Indicates Supply of Fuel by Magnet Principle.

The Hans Motor Equipment Company, La Crosse, Wis., manufactures a large number of designs of fuel

gauges, one of which, a tank design, is shown in an accompanying illustration. It is mounted with its float chamber directly in the tank, the dial case being the only part visible. The type is designed for machines where the fuel container is very accessible.

The indicating hand moves over a calibrated dial, and is operated by a magnet mounted behind the dial. The working parts are enclosed in an air tight and dust proof chamber, and the maker states that the construction is leak proof. All of the Hans products are carefully tested before being marketed.

PERFECTION TIRE PUMP.

A Two-Cylinder Design with Complete Equipment.

The Smith Perfection power tire pump, marketed by the Smith Motor Devices Company, Dodgeville, N. Y., is a two-cylinder unit, with the cylinders made of a high grade brass tubing, tested to a capacity of 400 pounds to the square inch. The heads are of special steam bronze to reduce heating to a minimum. The best grade of aluminum is used in the upper and lower crankcases and the main shaft is of chrome nickel steel with non-gran bronze bearings.

The bronze connecting rods are driven by means of an eccentric, a special drop forging, thus eliminating many parts. The die cast pistons have large wristpins, and compression packings prevent oil from reaching the air chamber. Gears, shifting lever, 15 feet of hose, pressure gauge and copper tubing are included.

X L CUT-OUT.

Cuts Out Exhaust by Means of a Movable Tongue.

The Auto Improvements Company, Bristol, R. I., has brought out a new design of muffler cut-out for model T

Ford cars, although it is stated that it will be constructed for other makes. The maker claims that it is superior to the conventional types in that it cuts out all of the exhaust by means of a tongue. The last named member, when raised by a pedal, forms a partition in the exhaust line, forcing the gases to pass out through a rectangular opening. The absence of back pressure when not in service is emphasized by the inventor, also ease of attachment. In the illustration the tongue is shown raised.

ATWATER KENT K-2 SYSTEM.

Includes Automatic Advance of the Spark and Reverse Switch.

The Atwater Kent Manufacturing Works, Philadelphia, has brought out a new ignition system termed the K-2 Atwater Kent. It embodies the latest development of each feature of the Unisparker system and includes the Atwater Kent automatic spark advance, which is held to increase the flexibility of the motor, make for economy, and relieve the driver of manual control of the ignition. A quality of the advance device is that the spark is always properly retarded for starting, and advanced for running in proportion to the piston speed.

Another feature of the system is the reversing switch, by means of which the direction of the current through the contact maker is changed each time the motor is operated, an arrangement augmenting the life of the contact points. There is

but one contact point to adjust, and it is stated that it will not require attention oftener than every 10,000 miles.

The complete system includes, in addition to the K-2 Unisparker, an "under-hood" coil, reversing switch and suitable length of double primary cable for making connection between the coil and Unisparker. The reversing switch is installed flush with the dash and is provided with a locking key and starting button if desired. The Unisparker must be mounted vertically on a substantial bracket or arbor and is driven at one-half crankshaft speed. Economy of current is one of the features of the Atwater Kent systems.

GEMCO SHOCK ABSORBER.

Ford Design Employing Coil Spring and Straps.

The Garage Equipment Company, Milwaukee, Wis., is marketing a shock absorber for the model T Ford car, which comes three to a set, two being utilized at the rear and one in front. It is claimed by the maker that the Gemco will control excessive spring action when traversing rough roads, impart easy riding qualities

and prevent breaking of the springs.

Both the front and rear members comprise spiral coils, two being used with each rear absorber. The coils are secured to the frame of the car, and from them extend adjustable, heavy straps, which pass under the rear axle. The upward movement, or recoil, which is held to be the most general cause of breakage, is restricted by the coils and strap.

The absorber used in front is fitted to the axle and the cross frame member, but its position is reversed; that is, the strap is placed over the cross frame and the coil clipped to the axle. The Gemco absorbers are moderately priced.

FORD ACCESSORIES.

In keeping with its policy to acquaint its readers with the latest accessories, The Automobile Journal makes in this department the first announcement of four devices for the model T Ford car. These include an anti-rattler for the steering gear connecting rod, fuel tank and radiator caps and number plate holders. Makers of Ford equipment are invited to forward data and illustrations of new devices.

DOVER DUPLEX MEASURE.

Combination Funnel and Measure of Sturdy Design.

The Dover Stamping & Manufacturing Company, Cambridge, Mass., is marketing the Dover Duplex combin-

ation measure and funnel, which possesses several practical features, the most noticeable of which is a pouring lip with a centre channel. This permits of fast pouring and in quantities. The opposite side has a funnel, which points slightly upward, so that when the measure is set down all lubricant runs back into it instead of outside.

The design differs from usual Dover practise in that the handle is placed on the side, which makes for convenience when filling oil reservoirs in close quarters or cramped places. As with all Dover measures, it is of correct capacity and conforms with the laws of the various states.

HERZ SHOCK ABSORBER.

Utilizes Swinging Movement of a Steel Lever.

Herz & Co., 245 West 55th street, New York City, has brought out a shock absorber which is held to be a distinct departure from previous designs. In the Herz the resistance necessary for the absorption of the spring vibration is produced by the swinging movement of a steel lever in a specially compounded substance. The maker states that the design is simple and that there is nothing to get out of order. The cast iron box containing the substance also retains the bearings for the inside lever, and is secured to the frame of the car. The outside lever with a ball on its end is attached to a rod having a socket end, and the rod in turn is secured to the spring of the car. It is stated that the Herz absorber has been in service abroad for the past four years. It is guaranteed.

A. A. A. FUEL TANK CAP.

Designed for Ford Cars and Has a Weather Proof Vent.

Among the new Ford accessories marketed by the A. Auto Appliance Company, Providence, R. I., is a neat-

ly designed fuel cap for the roadster type of car having the gasoline tank exposed. One of the qualities of the cap is the use of a small tit in its centre, which the maker states prevents the entrance of water when the car is operated in stormy weather and when it is being washed.

Another feature of the design is the incorporation of a channel around the edge of the cap, it being intended to catch any fuel that may be splashed out through the vent hole, thereby preventing gasoline from running over the container. The caps are constructed of the best grade of bronze and aluminum, and the standard finishes are highly polished nickel and black enamel. The cap not only makes for convenience, but adds to the appearance of the machine.

BUNGAY GEARSHIFT.

Speed Changes Are Secured by Automatic Means.

The Bungay automatic gearshift is marketed by the Bungay Manufacturing Company, Brooklyn, N. Y. Use is made of the energy contained in a compressed helical spring to shift the gears, and through the medium of selector discs and rods. The spring is compressed by the final half movement of the clutch pedal, after which the proper gear may be selected by means of a lever on the steering column. By fully depressing the clutch pedal the energy of the spring is utilized to shift the desired gear through the selector rod and the shifter rod in engagement with it.

The spring employed to shift the gears is shown at A, and is held between two selectors, B, which are controlled through their gears meshing with the gear C on a rod connected to the steering column control. During the final movement of the clutch pedal, the shaft D is moved forward, compressing the spring A in either direction, according to the

speed that is engaged, through the link E, levers F, and cross heads G and H. When in neutral, stops prevent the movement of the selectors and the release of the spring pressure. On the selectors being so turned, however, that one of their slots registers with a stop, the selector is allowed to move past the stop and engage a finger on one of the rods K, shifting the gear selected. The device is stated to weigh but 18 pounds and is adaptable to used machines.

DACO FORD ANTI-RATTIER.

Replaces Ball Socket Steering Gear Cap and Has Grease Cup.

The Danver Accessory Company, 18 Broadway, Pawtucket, R. I., manufacturer of Daco accessories for Ford cars, has brought out a new design of anti-rattler for the steering gear connecting rod. It differs from conventional devices marketed for taking up the lost motion in the ball and socket member, in that a grease cup is provided, making it possible to lubricate the working parts. A quality of the cup is that it locks automatic-

ally, preventing loss of the cup.

Play of the ball and socket is prevented by a coil spring, which carries a hardened steel plunger constructed to conform to the contour of the ball. This spring automatically maintains the proper tension at all times and absorbs shocks that would otherwise be communicated to the driver's hands. The maker states that adjusting means are not necessary as the plunger is hardened, and the parts subject to wear properly lubricated by the grease cup. The Daco combination anti-rattler and grease cup is constructed of high grade material, and all parts are accurately machined, insuring easy attachment to the steering gear connecting rod. It is moderately priced.

TIRE PUMPS.

That the power tire pump appeals to the motorist is denoted by the large number of letters received asking for specific information as to the practicability of installing it on used machines. Elsewhere in this issue will be found complete data on the subject of power tire pumps, as well as those of the spark plug type.

TYPHOON PUSH BUTTON.

Compact Steering Wheel Fixture for Electric Horns.

A very neat and compact type of push button for operating an electric horn is the Typhoon, manufactured

by the Typhoon Signal Company, Lincoln, Ill. One of the qualities of the design is that it may be attached to the steering wheel or to any flat surface, a clamp being provided for the first named installation. When attached to a flat surface, the clamp is discarded and two wood screws utilized.

The company is also marketing a steering wheel wiring fixture for electric horns. The leads are concealed, running through a tube alongside the column, with a bend on the upper end, being held by two brackets, and bringing the push button within easy reach of the driver. A flexible tube is employed at the bottom end of the fixture.

GRUS SPRING OILER.

Designed to Provide Constant Lubrication of Leaves.

Several designs have been marketed for forcing apart the leaves of the springs so as to lubricate the bearing surfaces, but a new method of reducing friction is noted in the device being manufactured by Wm. Grus, Jr. & Co., 5213 Wayne avenue, Chicago. The Grus patent leaf spring oiler is attached permanently to the spring, being fitted about one-third the distance from the centre, as shown in an accompanying illustration.

The plate, which is bolted to the side of the springs, is provided with an oil receptacle, which has an opening registering with the springs, and the maker states that the lubricant will automatically find its way to the bearing surfaces. The oiler proper is provided with a cap, which excludes all foreign elements. The device is made in varying sizes for different springs, and is moderately priced.

A. A. A. FORD RADIATOR CAPS.**Sturdy Design Having Scalloped Edges and Letters.**

The A. Auto Appliance Company, 114 West Exchange street, Providence, R. I., manufacturer and de-

signer of Ford specialties, will market, after March 1, several designs of radiator caps for the model T Ford automobile. One of the qualities of the caps is that they are cast, not stampings. They are constructed of bronze and aluminum, and have scalloped edges, which not only add to the attractiveness of the design, but facilitate removal and replacement. The corrugations are made to fit the fingers, providing an excellent grip.

The threads are accurately cut and the maker guarantees that the caps will fit all model T Ford radiators. They are made in two styles, one a plain cap, and the other with an initial. Two finishes are supplied, a highly polished nickel and black and nickel. The A. Auto Appliance Company is prepared to manufacture radiator caps for all standard makes of cars.

A. A. A. NUMBER HOLDERS.**Constructed for Front and Rear Plates for Ford Cars.**

The securing of the license number plates so that they will conform to the laws, and so that they will not vibrate or rattle, is more or less difficult with some types of machines. The A. Auto Appliance Company, Providence, R. I., is manufacturing two types of number plate holders for the model T Ford car, and the maker states that either can be fitted in a few minutes, and that the location of the holders is such as to comply with the automobile laws of all states.

The design for the front number plate is the smaller in the illustration, and it will be seen that it is provided with two arms or projec-

tions. These have holes, which are so spaced that the holder may be slipped over the threaded ends of the spring clips, and locked securely by the usual nuts. This makes for a rigid suspension. The number plate is bolted or secured by machine screws and nuts to the holder proper.

The larger design is for attachment to the rear spring, and it is secured in a similar manner to the front holder. Provision is also made for carrying the tail light, and a quality of the design is that the arm is sturdily constructed to withstand road shocks. The holders are made of malleable iron, and are finished in nickel or black enamel.

G-S SHOCK ABSORBERS.**Combine Spring and Compressed Air Principles.**

The G-S "Geschwa" shock absorbers are marketed by the Geschwa Importation Company, Hartford, Conn., and road shocks, vibration, etc., are compensated for by the combination of a spring and novel use of the compression of air. The spring employed is not an ordinary coiled member. It is a flat, highly tempered spring, coiled in a spiral conical form, as shown in the smaller illustration, and it is stated that when it is compressed it forms a pneumatic air

cushion, eliminating shocks, also controlling the rebound of the car springs.

An air chamber is provided at the bottom, this governing the spring suspension of the machine, and the compartment has a relief to equalize upward and downward movement. The arm attached to the shock absorber spring moves in a housing, and is secured to the lower spring when three-quarter ellipses are used, for example, while the top car spring is secured to a bolt extending through the housing of the absorber.

It is claimed by the maker that the G-S can be completely telescoped without affecting flexibility or efficiency, and that the design is unbreakable. It is also stated that it can be attached or removed with slight expense, and that it may be adjusted to varying loads. The G-S absorbers are sold with a guarantee for one year, and are made for varying spring suspensions and different makes of machines.

In writing for prices, etc., always mention The Automobile Journal.

WONDER TIRE DEFLATOR.**A Five-in-One Practical Combination Pocket Tool.**

The usual method of deflating an inner tube when in the casing and on the car, is to depress the valve

plunger, a process that takes time. The Sprick Bros. Investment Company, Stickney, S. D., is manufacturing what is termed the Wonder tire deflator, which is a combination tool, in that it may be utilized for five different purposes.

As will be noted by the accompanying illustration, one end of the tool can be clamped or snapped on the valve stem and by moving the lever toward the main body of the device the valve plunger is fully depressed, permitting the air within the inner tube to escape freely. The Wonder can be carried in the pocket and also serves as a Prest-O-Lite key, screw driver, valve plunger remover and bottle opener.

THE LOCK-ALL.**Electric Switch Locking Lights and Ignition.**

During the past six months a large number of locking devices, designed to prevent operation of the car by others than those intended, have made their appearance. Among the latest is the Lock-All, an electrical device, manufactured by the H. P. B. Electric Company, 500 Fifth avenue, New York City. It is an electrical switch and lock combined, very compact and neat in appearance.

The Lock-All controls the operation of the lights, ignition and electric horn, and the lock utilized is a Yale. The switch is also fitted with a central knob, which, when kicked by the driver, serves to direct the current from the head to the side lights, or vice versa, without removing the hands from the steering wheel. It is stated that the lights may be locked in any combination, and that the ignition circuit can be broken or magneto grounded and locked to prevent use of the car.

CORRESPONDENCE WITH THE READER.

Lubricating Systems.

Kindly explain, for the benefit of a non-technical automobilist, a reader of your book, the meaning of the terms used by manufacturers in cataloguing their lubricating

Fig. 1—Showing Leads Utilized in Pressure or Constant Circulating Type of Lubricating System.

systems. It appears to me a jumbled up mess of words. The catalogues speak of constant levels, automatic splash, circulating, pressure, etc. Which is which?

PERPLEXED.

Sioux Falls, South Dakota, Feb. 8.

Lubricating systems may be divided into two general classes, splash and pressure, and these combined. The principle of the splash system is one in which the ends of the connecting rods dip into an oil reservoir in the lower half of the crankcase, splashing the lubricant to the working parts of the motor. The system may include means for feeding the lubricant to the crankcase, such as a pump, or by utilizing the pressure of the exhaust to force the oil to the reservoir, etc. Provision may also be made to maintain a certain level of lubricant in the crankcase, and when such is the case the system is termed the constant level splash.

The pressure or constant circulating principle involves the delivery of the lubricant from the reservoir through piping to the main bearings, wristpins, etc., from which the excess oil gravitates back to the reservoir, whence it is again taken up by the pump and again circulated. The splash-pressure system is a combination of the two above described. There also is the non-circulating system in which the oil is used but once.

An example of the pressure or constant type is shown at Fig. 1, the illustration depicting the system employed on the Marmon car. It will be noted that the crankshaft and camshaft are drilled from end to end, and that there is an independent feed of oil direct from the pump to the seven main bearings of the crankshaft and to the ends of the camshaft. There are outlets for each

of the five bearings of each camshaft, similar to those through which the oil reaches the crankpins from the hollow camshaft. From the chief distributing points at the main bearings, the lubricant is conducted through the hollow crankshaft to the crankpins and from them to the wristpins, so that the oil is delivered under direct pressure to the parts. A gauge on the dash indicates the pressure under which the system is operating. The path of the lubricant is easily followed in the illustration by the black lines.

A combined system, which is catalogued by the maker of the car as automatic, is shown at Fig. 2. It is used with the Lozier motor. It provides the splash feature, as the lubricant is delivered to a trough under each connecting rod, the oil being forced to the vessel by a pump. These troughs tilt, being connected to the throttle linkage in such manner that at high motor speeds the ends of the connecting rods dip deeper. The oil levels at varying speed are indicated in the illustration by dotted lines. The linkage and oil reservoir are also shown.

Drive of Motor Starters.

Which is the better method of imparting the energy of the electric motor starter, by chain or by gear to the crankshaft or flywheel of the engine? PURCHASER.

New Haven, Conn., Feb. 15.

It is a matter of opinion. Both have their advantages and are used by representative car manufacturers.

Grinding Compound.

Can you give me a recipe for making a good valve grinding compound, one that will cut fast?

AMATEUR REPAIRMAN.

Denver, Col., Feb. 8.

An excellent and rapid cutting abrasive may

Fig. 2—Combined Splash and Pressure Feed Lubricating System—It Is Also Termed Automatic Because of the Use of Tilting Troughs.

be made by mixing oil with the finest of carborundum. If not familiar with its use it is best to use plenty of oil in grinding.

IN THE COMMERCIAL VEHICLE FIELD.

Result of Six Months' Service with Foden Steam Trucks in Contract Haulage in New York City---Details of Commerce Chassis---America's Longest Daily Haul.

AFTER operating two Foden steam trucks, made by Fodens, Ltd., Sandbach, England, for some six months, the Terminal Transport Company, Kingsbridge avenue and 236th street, finds that with a trailer it is possible to work these machines at an expense of 15 cents a ton-mile. Since these vehicles are the only ones of this make being operated in America, it will prove of interest to consider some of the factors which have been determined by this concern.

The Foden wagon has an engine of the compound type, the steam jacketed cylinders of which have bore of four inches, high pressure, and 6.75 inches, low pressure, and stroke of seven inches. The boiler is built along the lines of the horizontal locomotive boiler and is hydraulically tested to 350 pounds, for a safe, working pressure of 200 pounds. The firebox is made large to take either coke or coal, and the total heating surface of the firebox and tubes is 70 square feet.

Underneath the chassis is a 160-gallon water tank, permitting a supply sufficient for a run of from 15 to 20 miles. The pump discharges through a feed water heater at the left of the engine, into which exhaust steam is led. An injector also is fitted. A steam syphon at the right of the coal bunker, just back of the driver's seat, and 11 feet of hose, permit water to be taken from a brook or other source of supply en route.

A two-speed gear is provided, giving speeds of two and six miles an hour. Drive is by sliding gears on the crankshaft, and thence by roller chain of 2.5-inch pitch to a live rear axle. The radius rods are threaded right and left to permit adjustment of this chain. Two sets of brakes are fitted, in addition to the use of the lever in re-

verse position. The service brake acts upon the flywheel and is actuated by the foot, while the emergency band brake operates on a drum on the rear axle. Steering is accomplished in the same manner as with the ordinary road roller, the front axle being pivoted at the centre.

As will be noted by an accompanying illustration, the bodies are arranged so as to be dumped, and this may be accomplished either by hand or by steam. The body is hinged at the rear and the load may be deposited in one place or spread as desired. The trailers utilized by this concern were supplied by Scannell & Nephew of London,

Dumping a Load of Material from Foden Steam Truck by Utilizing Power of the Engine.

a firm of motor engineers with which Fodens, Ltd., has a contract for this class of work. They are connected to the truck by a long drawbar with a spring at the forward end, designed to take up all shocks. There is no provision for dumping the trailers, although the rear ends and sides are hinged at the bottom and open outwardly.

It may be stated that Foden wagons have been sold for so-called Colonial service in many parts of the world, and statements concerning these vehicles which have been received in this country have indicated that they were particularly well adapted for service where there were

Average Monthly Cost of Operating Two Foden Steam Trucks and Three Trailers.

Average cost a machine a ton-mile.....		0.15

no roads, in the generally accepted use of that term. The experience of the Terminal Transport Company, according to its manager, Robert L. Niles, Jr., has been that they are not adapted for use on poor roads.

He says it is necessary to have roads with good foundation, and he explains this statement by calling attention to the weight of the vehicle and the distribution of the load. The truck is rated at six to seven tons. Ready for the load the vehicle weighs approximately 7.5 tons. Study of the illustration will indicate that a large proportion of the load is carried by the rear axle. Mr. Niles says that the weight to which the rear axle is subjected is about 12 tons. He adds that this concentration of weight might be avoided when the use of narrow cleats and wide spacing on the steel tires is permissible to give traction, but the marking which results on asphalt and bituminous pavements precludes this type of driving wheel in the vicinity of New York. Fodens, Ltd., has produced vehicles of this capacity fitted with rubber tires for use in Great Britain, but Mr. Niles is of the opinion that the cost of such tires would be prohibitive when trailers were used. The foreign

trailers used by this concern also are steel shod.

The company has experimented with various kinds of fuel. Soft coal has been found best for making steam, but introduces smoke and cinders. Coke is clean, but has insufficient lasting qualities and is rather bulky. The cheaper grades of coal and briquettes are held to be absolutely worthless. The machines are using a mixture of Plymouth red ash stove coal and coke, about half and half by volume. The bunker holds about 300 pounds of this mixture, and for long runs extra fuel is carried in bags with the load. Mr. Niles says the average consumption is eight to 16 gallons of water and from 10 to 20 pounds of fuel to the mile, depending upon the condition of the road surface and the grades.

The ton-mile cost stated above is based on a daily mileage of 30. The cost figures presented herewith are taken from the report supplied by Mr. Niles to the treasurer of the company at the close of 1913. They represent a monthly average based upon the actual cost of the several items, although it is probable that there may be some variation in the matter of mileage from month to month. The report covers the cost of each item and its percentage of the total for the two Foden steam trucks and the three trailers owned by the company.

COMMERCE DELIVERY WAGONS.

Constructional Details of a Chassis Designed to Meet a Specific Demand.

Specializing on a single chassis, rated at 1000 pounds, the Commerce Motor Car Company, Detroit, maintains that its product has qualities that adapt it for a wide variety of service, while its design and construction are such that it can be

operated with a very large measure of economy. The concern was established three years ago for the purpose of producing a vehicle that should satisfy a general demand for those who used a single-horse wagon, but who sought to serve longer routes and a greater number of customers, minimizing time and extending the area in which

Plan View of the Commerce Delivery Wagon Chassis, Showing Friction Transmission, Etc.

business of this kind might be transacted.

The motor employed in the Commerce delivery wagon is a Northway, four-cylinder, water-cooled, L head type, cast en bloc, with bore of three inches and stroke of 4.5. This gives a rating under the S. A. E. formula of 14.2 horsepower, but the maker claims it will develop 20. Lubrication is by a combination of force feed and splash. Ignition is by Bosch magneto with fixed spark. The carburetor is an automatic float feed type.

Power is transmitted by friction discs to the jackshaft, and thence by chain to the live rear axle, in which is incorporated the usual differential. The service brakes are of the expanding type on the rear wheels, while the reverse of the friction transmission is employed for emergency purposes. The frame is of four-inch pressed steel channel section with five cross members.

ton, Mass. The round trip is 130 miles, and this is covered five days in the week, in direct competition with the railroad as represented by the Adams Express Company.

The Warren river oysters are highly esteemed and the Boston customers are anxious that they shall be shipped under such conditions as will preserve their delicacy of flavor. Under the plan, by which it was necessary to rely upon the Adams Express Company, seven separate handlings were required, and to insure forwarding by this method the tubs had to be in readiness by 4 in the afternoon. The consignees demanded that the deliveries be made at 7 in the morning, but in point of fact deliveries were made anywhere between 7 and 12.

Last September Mr. Cotrone visited the Warren growers and interviewed the Boston consignees, with the result that he decided to under-

Two Peerless Trucks Utilized by Frank Cotrone & Co., Providence, R. I., in Making America's Longest Daily Haul.

The springs are semi-elliptic, those at the rear being outside the frame and shackled at either end. The driver is placed at the left.

This chassis is fitted with four body types, these being an open express with flare boards, express with standing top enclosed by curtains, a full panel with rear doors or end gate, and a stake platform.

COMPETING WITH RAILROAD.

Interesting Service Involving What Is Held to Be America's Record Daily Haul.

What is believed to be the longest daily haul by motor truck in America is that made by the two Peerless trucks owned by Frank Cotrone & Co., Providence, R. I., engaged in the transportation of oysters between Warren, R. I., and Bos-

take the delivery of oysters by motor truck over the road. Under the present plan the tubs are in readiness at any time between 4:30 and 6:30 in the afternoon. One of the trucks is of five-ton capacity and the other of four. One hundred tubs can be packed into the former and 80 into the latter.

After loading the trucks are taken to the garage in Providence, where they remain until midnight. Five hours are allowed for the running time between Providence and Boston. Deliveries are made before 7, and all empties are picked up. The trucks usually are back in Providence by 1 in the afternoon, and sometimes at 12, noon. Since no deliveries are made on Saturday, the trucks are not in service between Saturday noon and Monday noon, so that any necessary work may be done on them at that time. In addition, the drivers go over the machines each night.

MACHINERY, TOOLS, EQUIPMENT AND SUPPLIES.

HERZ & Co., electrical engineer, is marketing the Herz patented automatic time adjustment for ignition apparatus. It is designed not

Herz Automatic Time Adjustment for Ignition Apparatus Up to 40 Degrees.

only to prevent accident through back firing, caused by improper advance of the spark, but it is held to make for economy in the operation of pleasure and commercial vehicles. The time of ignition is adjusted automatically in accordance with the number of revolutions, and the range is up to 40 degrees.

The components of the device are shown in an accompanying illustration and it will be noted that it comprises a coupling consisting of two juxtaposed discs, the construction being interposed between the magneto and driving shaft. Each disc is provided with five grooved curves running in an opposite direction to those in the other disc. Five steel balls are held in these grooves and function in a similar manner to the weights of a governor, being forced outward by centrifugal force in direct proportion to the speed of the motor. The maker states that this construction imparts a twist to the armature of the magneto in relation to the driving shaft.

It is held that any desired degree of adjustment may be obtained by altering the curves in a suitable manner, and that the absence of springs, journals, joints, etc., and the certainty with which the balls are guided, make for reliability of operation.

The device is supplied either as an integral part of the ignition apparatus or in the form of a coupling. Owing to the small space it occupies it is stated that in many instances it can be used in place of the ordinary coupling and without alteration. All parts are made to gauge, are interchangeable, and constructed of the best of ma-

terial. Special literature is issued by the company and will be sent free on request.

O. K. TOOL POST.

The O. K. Toolholder Company, Shelton, Conn., of which C. Hilterbrant, 99 Nassau street, New York City, is direct representative, is manufacturing the O. K. tool post holder, shown in an accompanying illustration. It holds the tool on the side, thus enabling one to get up near the chuck or face plate. With this tool post the tool is adjusted vertically, thus maintaining the clearance on the cutting tool. The tool post swings around at any angle.

It is stated by the company that after placing it in the desired position, the process of tightening has no tendency to twist the tool post, and that the bolt is made to fit the T slot so that there is no danger of injuring the same. The nut is made to fit the tail stock wrench.

When it is necessary to grind the tool and it is desired to remove the tool or holder, the vertical adjustment is not affected. By swinging the tool post around at right angles and using a small V block, it is held that the design makes the strongest kind of a boring tool holder. All parts are steel drop forgings, carefully machined, case hardened and interchangeable.

The O. K. is made in three sizes, the No. 1 post being suitable for 14 to 18-inch lathes, the No. 2 for 20 to 28, and the No. 3 for 30 to 40. The tool post No. 1 is adapted for holders from one inch to 1.5 high and any width, the No. 2 from 1.25 to 1.75 high, and the No. 3 from two to 2.5 inches high and any width.

The O. K. Tool Holder Company also manufactures the O. K. system of tool holders, and tools for lathes, planers, shapers, boring mills, etc.

O. K. Tool Post for Holding Tool on the Side and for Adjusting It Vertically.

TRI-PHOON GARAGE PUMPS.

The Green & Swett Company, 737 Boylston street, Boston, is manufacturing the Tri-Phoon

Triphoon Electrically Driven Garage Pump.

garage pump, which is not only moderately priced, but is very small and compact, occupying but little room in the garage. One of the qualities of the pump is that it does not require the use of a pressure tank, as tires can be inflated directly and

very quickly. The cost of operating is slight.

The pump is made in three and six-cylinder forms and the motor employed for the smaller size is constructed for either a direct or alternating current. The six-cylinder unit is also marketed for either direct or alternating current.

One of the features of the Tri-Phoon is that it may be driven at a high rate of speed without injury to the working parts. As shown by the accompanying illustration, it includes a .25 horsepower electric motor, suitable length of flexible cord with plug, hose, pressure gauge and switch. The equipment is mounted on a substantial platform truck, which has a convenient handle for moving it about the garage.

The Tri-Phoon garage pumps are adapted for both private and public garages, and the guarantee is very liberal, the maker offering to replace free of charge any pump found to be defective or faulty in construction within a year. Descriptive matter will be supplied upon request.

PAINTING THE CAR.

Outfit for Ford and Small Car Owners Is Marketed by Northwestern Chemical Co.

Owners of small cars, especially those who care for their own machine, will be interested to learn that the Northwestern Chemical Company, Marietta, O., has brought out a complete equipment for painting Ford and small machines. Not

only does the outfit include all material, such as paints, brushes, sandpaper, etc., but complete directions are given, which if followed, will enable one to turn out a job to compare favorably with that of an expert.

The color card gives option of six colors, these being red, blue, orange, tan, gray and green. An outfit for painting both the chassis and body black is marketed, retailing at 75 cents less than the other colors.

The sample colors are rich and the finish is high grade in every particular. The outfit includes one can each of the following materials: Body color varnish, body color paint, black pigment varnish, top and upholstery dressing, gloss black brass enamel, gloss black engine enamel and mahogany varnish stain. The brush equipment is sufficient for using all of the above and without employing one brush for two materials.

The directions accompanying each outfit, which is moderately priced, are so given that it is a simple matter for anyone not familiar with painting to obtain excellent results. The different steps of the work are outlined and explained: in fact, instruction is given for preparing the room in which the painting, etc., is to be done.

The following concerns have been elected to membership in the Motor & Accessory Manufacturers: Michigan Steel Casting Company, 248 Guoin street, Detroit; New Haven Clock Company, New Haven, Conn., and Standard Tool Company, 6918 Central avenue, Cleveland, O.

Pioneer Outfit, a Complete Equipment for Painting Ford and Small Cars.

gress of March 3rd, 1879.

THE BOSTON SHOW.

Interest in the forthcoming Boston automobile show, especial reference at this moment being made to the pleasure car section, in every branch of the motor vehicle industry has been greatly increased by the fact that all automobile shows held thus far this year have created new records in the matter of attendance and business transacted. The annual Boston show has for many years been regarded as the best possible barometer by which to judge of the possibilities for business during the ensuing season. The fact that other shows have indicated splendid possibilities for the 1914 season only tends to enhance the importance of the Boston display.

At this writing, the applications for space are such as to indicate beyond doubt that the 1914

Boston show will retain its position of leader in number of makes and models of cars on exhibition. Since 1910, this New England display, although designated as a local dealer's exhibition, has not only been the largest in this country, but the largest in the world. In the matters of attendance and volume of sales, it has established a record which no other has been able to reach.

New England has long been conceded to be the world's best market for motor vehicles and their accessories, supplies and fittings. This is still true, despite the wonderful progress that has been made in other sections of the country during the past few years. The people are regarded as conservative, particularly in making investment, and it is for this reason that the sales consummated during the annual Boston show have been adopted as the criterion.

Insofar as the commercial vehicle display is concerned: This will be the only exhibition of power wagons of national importance this year. The term national importance is used advisedly, for, although the Boston show always has been a local display, its size, in every respect, has been such as not only to make it a national, but an international, event. Manufacturers have long been aware of this fact and have aided the local dealers in bringing about the splendid results obtained. It is expected that they will take every advantage of the opportunities afforded by this exclusive commercial vehicle display to present the merits of their product in a field where the possibilities are virtually unlimited.

Boston is so easy of access from every portion of New England and the Maritime Provinces of Canada that there is certain to be a larger attendance than ever before, particularly because of the increased interest in motor vehicles in the latter district. That none will be disappointed in the exhibition itself, is evidenced by the list of exhibitors and the products they will display, appearing elsewhere in this issue. Several new makes of cars and dozens of new accessory lines will be presented. Manager Chester I. Campbell and the members of the Boston Automobile Dealers' Association and the Boston Commercial Motor Vehicle Association are to be congratulated upon the success which has attended their efforts in connection with the 1914 Boston show—which promises, in every respect, to be bigger and better than ever.

GASOLINE PLEASURE CARS FOR 1914.

A Buyer's Guide to Makes and Models Produced by the American Industry for the Coming Season---Detailed Mechanical Specifications, Body Types and Prices.

PROSPECTIVE purchasers of gasoline pleasure cars will find the tabulations on the succeeding pages the most complete compilation of specifications concerning the various makes and models in the market for the 1914 season that it is possible to present. The information from which these tables were prepared has been supplied by the manufacturers and represents the very latest available.

There has been radical departure from the practise, which applied generally at one time, of announcing new models at the national automobile shows in New York and Chicago. Very few concerns now present yearly models as such. This situation may be held to be due in no small measure to the rivalry among manufacturers, which ultimately found expression in making such announcements for the succeeding year soon after the annual show season was closed. Under the new arrangement, changes in designs and construction are made public whenever manufacturing conditions seem to warrant.

During the past few years it has been decidedly noticeable that many of these changes have appeared in connection with the Boston show, which is held at the very beginning of the active driving season, and at a time when the public is prepared to make up its mind with reference to any possible purchases. It follows, therefore, that specifications presented in conjunction with the annual Boston show represent the latest developments of the industry—a dependable buyer's guide for the coming year.

Explanation of Tables.

Some little thought has been given to the presentation of these specifications, with a view to assisting the prospective purchaser in making comparison of the various models. In the tabulations devoted to the mechanical details of the several chassis, care has been taken to separate the four-cylinder and six-cylinder cars. Incorporated with these details are the prices and maximum seating capacity of the runabouts, roadsters, etc., on the one hand, and the touring cars on the other. This arrangement is expected to facilitate comparison of various cars at or about the same price.

Following the detailed specifications are presented a number of tables giving the price, seating capacity, wheelbase and tire sizes for en-

closed cars and other special body types, again sub-divided as to the fours and sizes, so that immediate comparison may be made on this score. It will be understood, of course, that the name of make and model will serve as sufficient key to determine the chassis details for these machines, as presented in the larger tabulation. Taken together, these tables present a complete index to the American gasoline automobile industry for the 1914 season.

The addresses of the various manufacturers will be found on the next page. This list includes practically every maker at all prominent in the industry. This statement must be qualified to some extent, because of fact that new concerns are being announced frequently. Some have entered the field since the work of compiling these statistics was begun. Others have been reorganized and information concerning their new product is not available at this time.

Analysis of Specifications.

Analysis of the tables shows another important trend in the industry. Of the 104 makers of four-cylinder chassis, producing a total of 139 models, 58 are manufacturing fours exclusively, and of these 34 make but one chassis model. Included in this classification is the Willys-Overland Company, which is listed as producing both the Overland and the Willys-Knight.

The list of six-cylinder chassis shows a total of 76 makers and 110 models. Of these, 33 makers are producing six-cylinder chassis exclusively, and 18 of these make but one model.

Added to those already mentioned, are the 16 makers of fours and sixes, which produce one chassis model of each type. Included in this classification are the American Voiturette Company, making the Car-Nation and Keeton, and the Lexington-Howard Company, producing the Lexington and Howard.

In many instances, where the same concern is producing a four and a six, the bore and stroke of the two motors are identical. This classification might be extended still further, if those makers who produce chassis, differing only in the wheel-base, were added.

Other features indicated by the tabulations include the general adoption of electric lighting and some form of starter, usually electric, as well as the preponderance of the left hand drive.

Detroit—\$850 without starter. Fiat 55—Rear tires, 37x5. Hupmobile—\$1050 and \$1200 without starter. King—\$1095 without starter. K-R-I-T—\$950 without

SPECIFICATIONS OF 1914 FOUR-CYLINDER CARS.

Key to Abbreviations: Cylinder type—L, valves in the head; L, L head; T, T head. How cast—B, on bloc; P, in pairs; S, separately; T, in triplets. Lubrication—C, combination; P, pressure; S, splash; SP, splash with pump circulation. Cooling—A, air; P, pump; T, thermo-siphon. Fuel feed—G, gravity; P, pressure. Carburetor—Car, Carter; Flet, Fletcher; Hol, Holley; King, Kingston; Mar, Marvel; May, Mayer; New, Newcomb; PL, Pineshard; Ray, Rayfield; Sch, Schaefer; St, Stromberg; Zen, Zenith; Zep, Zephyr. Ignition—A, K. Atwater Kent; Bos, Bosch; Br, Briggs; Conn, Connecticut; Del, Delco; Elia, Elsmann; King, Kingston; Mich, Michigan; Nat, National; Sim, Simms; Spl, Splittdorf; West, Westinghouse. Clutch—C, cone; CB, contracting band; D, disc; EB, expanding band. Transmission—F, friction; PL, planetary; Pr, progressive; S, selective. Rear axle—D, dead; F, full floating; 1/2, semi-floating; 3/4, three-quarter floating. Starting and lighting—G & D, Gray & Davis; Leeco-N, Leeco-Neville; N, East, Northeast; Rush, Rushmore; Ward-L, Ward Leonard; West, Westinghouse. Driver—L, left; R, right; O, optional.

FIVE-PASSENGER FOURS.

- 1—Moline-Knight; wheelbase, 128 inches; \$2400.
- 2—Regal Underlung T; wheelbase, 108 inches; \$1125.
- 3—Overland 79-T; wheelbase, 114 inches; \$950.
- 4—National Series V-3; wheelbase, 128 inches; \$3300.
- 5—Marmon 32; wheelbase, 120 inches; \$3000.
- 6—Haynes 28; wheelbase, 118 inches; \$1985.
- 7—White 30; wheelbase, 110 inches; \$2500.
- 8—K-R-I-T; wheelbase, 108 inches; \$1050.
- 9—Maxwell 25-4; wheelbase, 103 inches; \$750.
- 10—Reo the Fifth; wheelbase, 112 inches; \$1175.
- 11—Cartecar 5A; wheelbase, 116 inches; \$1700.

SPECIFICATIONS OF 1914 SIX-CYLINDER CARS.

Key to Abbreviations: Cylinder type—L, valves in the head; T, L head; T, T head. How cast—B, en bloc; P, in pairs; S, separately; T, in triplets. Lubrication—C, combination; P, pressure; S, splash; SP, splash with pump circulation. Cooling—A, air; P, pump; T, thermo-siphon. Fuel feed—G, gravity; P, pressure. Carburetor—Car, Carter; Flat, Fletcher; Hol, Holley; King, Kingdon; Mar, Marvel; May, Mayer; New, Newcomb; PL, Planhard; Ray, Rayfield; Sch, Schaebler; St, Stromberg; Zen, Zenith; Zep, Zephyr. Ignition—A. K., Atwater Kent; Bos, Bosch; Br, Briggs; Conn, Connecticut; Del, Delco; Eise, Eise-mann; King, Kingston; Mich, Michigan; Nat, National; Sim, Simms; Spl, Splittorf; West, Westinghouse. Clutch—C, cone; CB, contracting band; D, disc; EB, expanding band. Transmission—F, friction; PL, planetary; Pr, progressive; S, selective. Rear axle—D, dead; F, full floating; 1/2, semi-floating; 3/4, three-quarter floating. Starting and lighting—G. & D., Gray & Davis; Leece-N., Leece-Neville; N. East, Northeast; Rush, Rushmore; Ward-L., Ward Leonard; West, Westinghouse. Driver—L, left; R, right; O, optional.

DECISION IS REVERSED.

Court of Appeals in France Takes Different View of Motorist's Rights.

Last November, a chauffeur who was driving his master's car, was approaching a small village in France when he noticed three men standing by the side of the road. Just as he was passing them one of the three suddenly stuck a long pole between the spokes of one of the wheels of the car, stopping it so suddenly that it was all the driver could do to keep his seat.

A few days later he was surprised to receive a summons, charging him with violence and exceeding the speed limits. Then he learned that the individual who had thrust the pole between the spokes of his wheel was no less a person than one of the municipal councillors of the village.

Naturally, the chauffeur claimed that the councillor had no right to take out a summons charging him with exceeding the speed limit, and still less to act in such manner as to endanger the lives of those using the highways. The court was not of this opinion, deciding that a private

citizen has a perfect right to stop a car in the manner in question when it is alleged to be travelling at an excessive speed. The case was appealed and the Amiens court of appeal has reversed the decision.

GRANT COMPANY'S OFFICERS.

Plans for Coming Year Include Material Increase in Production of Cars.

At the annual meeting of the Grant Motor Company at its new plant in Findlay, O., Feb. 10, the following directors were re-elected: D. Grant, Charles A. Grant, David A. Shaw, George S. Waite, George S. Salzman, James M. Howe, H. J. Koehler and A. Freschl. The officers are: President and treasurer, David A. Shaw; vice president, Herman J. Koehler; secretary and sales manager, George W. Waite; factory manager, George S. Salzman; engineer, James M. Howe.

The factory has been shipping an average of 20 cars a day, and plans have been perfected, under which this production will be greatly increased at once.

STATIC CONDITIONS IN IGNITION SYSTEMS.

MOTORISTS, when seeking to locate the cause of a baffling, intermittent miss, and when the components of the ignition system do not reveal any apparent fault, have noted when running the engine in the dark that the cause of the trouble was due to the high-tension current jumping from one of the secondary cables to nearby conducting material. And it is not unfrequent that an examination of the insulation does not reveal any chafed or broken places.

It is well known that the voltage of the initial or primary current must be built up so as to bridge the air gap between the electrodes of the spark plug, and that a high potential discharge is necessary to overcome this resistance. It is also a fact that anything which tends to retard this high potential discharge reduces the efficiency of

ter wheel, this wheel being connected with machinery, which requires considerable effort to start, but after once in motion, the actual effort required for operating purposes is less. The water tank is placed at a proper height to obtain the lower pressure; but to obtain the higher initial pressure—the one required to start the wheel—a pump is installed near the tank and so arranged that it will draw water from it, then force it to the water wheel at the required high pressure.

High and Low Pressures.

After the high pressure fluid is sent through the pipe, it is immediately followed by the lower or tank pressure, means being provided at the pump to accomplish this effect, as indicated in the drawings at Figs. 1 and 2. The pipe conducting the water from the pump to the wheel is of a

Fig. 1—Illustrating an Analogy Between Water Flow and High Voltage Discharges, insofar as They Affect and Apply to Ignition Systems.

the ignition system, as in the case of the jumping current cited, and results in a weak spark at the plug. In pronounced cases these conditions may cause missing or even back firing.

Static Conditions.

The Bosch Magneto Company explains some of these conditions in The Bosch News for February, and the data are based on the results of years of experience with high-tension ignition systems. Much of the misfiring and back firing is attributed to electrostatic charges and discharges, which are more commonly known as static conditions, being set up by the discharge of high potentials, or high voltage.

An explanation is made of electrostatic conditions, insofar as they apply to ignition systems, by drawing an analogy between water flow and high potential or high voltage discharges. For example: Suppose a pipe is to be used for the purpose of carrying water from a tank to a wa-

porous material, and has certain frictional irregularities which tend to retard the initial water flow. Consequently, a certain amount of the high pressure power will be used in satisfying the effects of the porous material and overcoming the frictional conditions, in order that the lower pressure flow or power will be uninterrupted.

The amount of water that can be absorbed by the porous pipe is called its capacity. If a second pipe of the same material be placed alongside the first pipe, so that their surfaces are in contact with each other, a further amount of water will be absorbed. If the porosity of this second pipe were sufficient, it would allow a quantity of water to be absorbed, great enough to cause an actual flow out of its end. If other bodies of a porous nature were brought into contact with these pipes, it would result in a large amount of the initial flow being necessary to satisfy this capacity or porosity, and would necessitate a higher

initial pressure at the pump, in order to obtain the same power at the water wheel as would be true if these conditions did not exist.

Porosity of Pipes.

It can be seen that this condition of porosity requires that a considerable amount of energy be uselessly expended, in order that the high initial pressure may be obtained, and therefore the amount of power exerted on the water wheel is not in proportion to that leaving the tank. The only method whereby the greatest efficiency could be obtained would be to have the pipe in which the water flows constructed of material which was not porous. If this were not possible, then it would be necessary to have the porosity of the pipe held down to the lowest degree possible, and to keep away from it other porous bodies, so as to prevent the possibility of absorption taking place. It would be necessary also to have the inside of the water pipe free from conditions which tend to create friction.

sufficient to cause the water wheel to start revolving, and a further outward movement of the crank will cause the boss C to engage the stem of the valve G. Fig. 2 D shows the valve G open, and the piston in such position that the valve F is blocked off. On account of the valve G being open, water will flow from the reservoir in the direction shown by the arrow, into the porous pipe H to the water wheel, and keep it revolving. This cycle of work takes place once in each revolution of the pump's crankshaft. The varying pressures that will result are shown by means of the curve at Fig. 3, a similar wave or curve being obtained from high-tension ignition systems.

Absorbing of Current.

The conditions explained are analogous to those in high-tension ignition circuits as employed on internal combustion automobile engines. Although the cable insulations in the true sense of the word are not porous, they have the ability to absorb an electrical charge, the same as

Fig. 2—Illustrating an Analogy Between Water Flow and High Voltage Discharges—The Low and High Pressures Are Utilized to Show the Dynamic Current and High Potential Discharge.

Figs. 1 and 2 show the four positions of a power plant, these being used to illustrate the various effects above described. The drawing at Fig. 1 A shows the relative position of the valves and piston of the pump, previous to operation. A is the tank, B the piston and E the inlet valve. The piston in travelling outward permits a quantity of water to be drawn from the tank. Valves G and F are closed. Fig. 1 B shows the position after the piston has drawn in the water, and is in the act of forcing it out through the valve F, thereby creating a high pressure in the porous pipe H. During this operation valves E and G are closed.

Varying Pressures.

Fig. 2 C gives the positions just at the completion of the high pressure period. Valves E and G are closed and the cylinder is practically empty of water, but the high pressure which was due to the movement shown at Fig. 1 B has been

a porous pipe absorbs water. This condition is also known as capacity, and the greater amount of dielectric, or insulating material, the greater the capacity.

In place of the high pressure water discharge there exists what is known as the high potential or high voltage discharge, and that which corresponds to the lower water pressure discharge is known as the dynamic or true amperage flow. At the instant that the high potential discharge is released from the magneto armature secondary winding and sent through the cable that is in connection with the spark plug, it results in this cable taking on or absorbing a part of the electrical charge. According to the laws of electricity, this charge is capable of causing other bodies to become charged when brought in surface contact with the cable that carries the high potential discharge. If other surfaces are in contact and no means are provided for discharging this static

condition, it may become sufficiently intense to cause a spark to occur in a cylinder that is not in a firing position. This results in back fires, and

Fig. 3—Curve Showing Pressure Period in Pipe Line—A Similar Wave Is Obtained from High-Tension Ignition Systems.

sequence, if the magneto or ignition source does not supply an extremely high potential, there will not be sufficient energy to cause the current to bridge the gap at the electrodes of the spark plug.

High Potential Discharge.

The purpose of the high potential discharge is to bridge the gap and create a path over which the lower voltage or dynamic current can flow. This fact proves that anything which tends to retard the high potential discharge will tend to the detriment of the ignition system. The Bosch Magneto Company states that if ignition systems are installed so that the high-tension leads are twisted together, or are carried in a container that is insulated from the metal part of the motor, it will result in unsatisfactory operation.

The best results are held to be obtained when the individual cables are separated one from the other. If this is not feasible their surfaces must be given a perfect ground. The cable lengths should be as short as possible, loops or frequent twists about the parts of the motor or chassis avoided, also sharp bends or angular curves. Precaution should also be taken to prevent the possibility of chafing. This is very important.

Proper Insulation.

Relative to the thickness of the insulation: The average person believes that the thicker or heavier the insulation the less liability there will be of trouble. While this seems reasonable, states the Bosch company, yet added insulation increases the capacity of the cable and thus static conditions are considerably encouraged. Medium thickness and proper quality of insulation are important factors in the selection of cable for ignition purposes.

Wire Suspension.

The wiring arrangement shown at Fig. 4 A is recommended, the only drawback being the lia-

bility of the cables becoming disarranged or damaged, as the average space under the bonnet of a small car is limited. If the space permits of the arranging of the cables in a similar manner and the use of a metal covering, the method would be excellent. This system, a Bosch, is utilized by a number of manufacturers abroad. Fig. 4 B shows an installation somewhat similar to that at A, but it is possible to carry the wires more closely together, due to the fact that the surface of the cables are grounded at regular intervals. Lack of space, however, does not always permit of the installation.

From the above it will be seen that too much care cannot be given to the arrangement of the cables carrying the secondary current; that they should be well separated from one another, and means provided for discharging any existing static condition.

PAYMENT ON KRIT EXTENSION.

General Manager Reports Business of Company Is in a Prosperous Condition.

Announcement is made by the Krit Motor Car Company, Detroit, that the February payment on the extension, arranged some time ago, has been met. This is the first installment to fall due and its prompt payment is expected to still further place this concern in a position to take care of its rapidly increasing business. General Manager Howard Crawford has the following to say with respect to the condition of the Krit company:

We have never had so many orders on our books as now. At present we are working to bring our production to meet the big demand for Krit cars. After

Fig. 4—Wiring to Prevent Static Conditions: A, Method Recommended and Used Abroad; B, Plan Not Always Possible Due to Lack of Space.

March 1 our output will easily be greater than ever before, with factory working at full capacity. Already, we are taking on more men, and in some departments are working nights.

DUELEC NUMBER 2.**An Electric Vaporizing Primer, Operated from Seat and Easily Installed.**

The effect of low temperatures on gasoline is well known to motorists, and with the present

Duelec Vaporizing Electric Primer.

grade of fuel difficulty in starting is more pronounced than formerly. The chief trouble experienced is that the fuel does not vaporize readily, resulting in too thin a mixture to ignite. And in low temperatures, priming the cylinders with raw fuel does not always obtain readily the desired results.

By raising the temperature of the fuel to a point where it vaporizes easily, starting is made easy, because the vapor mingles readily with the air, forming a homogeneous mixture—one that ignites quickly. This is the principle involved in the Duelec vaporizing primer No. 2, which is being marketed by the Duelec Vaporizing Primer Company, 14 North Broadway, Yonkers, N. Y. Instead of injecting raw fuel into the intake manifold or combustion chamber, the Duelec device heats the gasoline by electricity and to such a temperature that the results obtained are similar to those on a hot, summer's day.

The device is simple, very compact and easily installed. As will be noted by an accompanying illustration, the Duelec comprises a heating chamber in the form of a cylindrical porcelain or fibre, in which is incorporated a resistance coil. The last named is retained by two terminals to which the leads from the battery or other source of current supply are secured. Below the coil is a fuel valve or petcock, which, when opened, permits access of fuel from the main line.

This valve is controlled from the switch, push button, lever or other means of current control, the one operation opening the valve, admitting fuel, vaporizing it, and shutting off the valve and supply when the circuit is broken. This is performed from the seat with motor starters and in a similar manner when the engine is cranked. The

switch unit is connected by a rod having a universal joint, so that the control member may be placed as desired, making for convenience.

The installation is a simple matter. An .125-inch hole is drilled and tapped in the intake manifold and the Duelec attached. The main line is also tapped and a pipe led from it to the Duelec by means of a solderless tee connection. The control rod and switch member are then fitted, and the wires attached. One of the qualities of the Duelec is that it may be inverted to facilitate installation. It is stated that it requires but little current to vaporize the fuel, and that ignition cannot take place, as the coil cannot overheat the fuel. The Duelec is moderately priced.

RUSCO SPECIALTIES.**Russell Manufacturing Company Marketing Special Ford Lining and Rusco in All Widths.**

The Russell Manufacturing Company, Middletown, Conn., is marketing the Rusco brake lining and Rusco Ford specialties. The latter is a special material for lining the transmission brake of the model T Ford car, and one of its qualities is that it is woven without wire, which prevents any opportunity of short circuiting the Ford flywheel magneto.

The Rusco Ford lining is woven of a long fibre asbestos, and thoroughly impregnated with a special compound which renders the material water, oil and heat proof. A very high coefficient of friction is claimed for the Rusco brake lining, which is manufactured in widths from one inch to eight and in thicknesses from .125 to .5 inch.

The Ford lining comes in proper lengths to fit the transmission

band, is put up in a neat box, and copper rivets for applying are included in the equipment. The company

also specializes in a fan belt for the Ford machine. It is woven endless, is guaranteed to give perfect service, comes in a compact box and is inexpensive. Descriptive matter will be sent on request.

The Duelec Attached to Intake Manifold.

WITH THE CYCLECAR MANUFACTURERS.

Brief Details of Some Early Designs, and Confusion of Types Which Has Resulted in Great Britain---New Models Brought Out Recently in This Country.

IT IS pretty generally conceded in the industry that the first cyclecar was the Bedelia of France, which appeared on the streets of Paris

Latest Model of the Lad's Car, First Marketed in 1912.

in the latter part of 1910. Undoubtedly, others were experimenting along similar lines previous to the success of M. Barbeau, who designed and built this machine. In America the effort would seem to have been along the line of providing a practical machine for the use of children, as exemplified by the miniature National roadster provided for Master Thomas Hoyt of Cleveland O., by the designer of the present day Falcon cyclecar, Francis R. Hoyt.

Hoyt's Miniature Roadster.

This roadster, an illustration of which is presented herewith, first appeared on the streets of Cleveland in 1910, about the same time as the initial announcement of the Bedelia. It was patterned after the famous No. 4, National racer, in which John Aitken was at that time winning contests throughout the country. It was complete in every detail, with the exception that the motor was electric, and it possessed a real clutch, two brakes and a dummy shifting lever. Master Tom demonstrated that it was capable of traveling six miles an hour, and it was in every way a practical machine. There is very little doubt that there were others of a similar character, but this has been selected solely as an example of the forerunner of the American cyclecar.

Some time later the Niagara Motor Car Corporation, Niagara Falls, N. Y., placed the Lad's car on the market. No attempt was made to call this a cyclecar. Rather it was introduced as a practical machine for boys. One of the latest models is shown herewith. The Bedelia was described as a miniature automobile built along the

simplest lines. It will be noted that the Lad's car fulfills this condition.

Bedelia and the Lad's Car.

The Bedelia was fitted with a body, which at the same time served as the frame for the car. The wheelbase was 100 inches and the tread 36. The front axle pivoted at the centre on the spring tube B. The motor, a twin-cylinder motorcycle engine, was fitted in the frame, just back of the front axle. A chain A connected a sprocket on the engine shaft with a sprocket S on the countershaft. There was no clutch. On the ends of the countershaft were pulleys C, taking V motorcycle belts D, which transmitted the power to pulleys P, fastened directly to the rear wheels. The rear suspension was by Lanchester cantilever type springs. The rear axle was fitted to be moved forward and backward by the lever L, providing a variation in speeds by tightening and loosening the belts and doing away with the necessity for a differential. Steel cable, running from the front axle on either side, passed through pulleys and to a drum on the steering post, so that by turning the steering wheel W the cable on either side was pulled. The gasoline tank T was mounted directly over the engine. The weight of the car was less than 400 pounds. The two passengers were arranged tandem, in hammock type seats, the driver at the rear.

Such, in brief, were the mechanical details

Practical Miniature Automobile Produced in Cleveland, O., in 1910.

of the first cyclecar. The Lad's car has a single-cylinder motor of the T head type, with bore of 3.5 inches and stroke of four. Cooling is by

air, ignition by dry cells and the carburetor is a Schebler. The machine is fitted with a cone clutch and the transmission of power is by V belt from the countershaft to the rear wheels. Brakes are of the external contracting type, acting on the countershaft. Full elliptic springs are utilized front and rear. The wheels are 22 inches in diameter, fitted with Goodyear solid tires of one-inch cross section. The wheelbase is 72 inches and the weight, 385 pounds. Provision is made for but one passenger.

Cyclecars Here and Abroad.

The Lad's car was placed in the market late in 1912, but no one seems to have considered it a cyclecar. The name chosen would imply that it was designed as a machine suitable for the use of boys, but there can be no denying that it was an automobile built along the simplest lines. It was not until the middle of 1913 that the American cyclecar, as such, began to attract public attention, and even then the Lad's car appears to have been forgotten by the industry.

Soon after the initial appearance of the Bedelia, Great Britain began to experience wide interest in the new type of automobile. For a time it appeared that greater progress was being made in that country than in any other. Over 100 makers are listed in the United Kingdom, but decided confusion has resulted from the fact that the terms cyclecar and light car were used indiscriminately. And it is worthy of note that a much similar condition has arisen in this country.

In the last issue of *The Automobile Journal* the organization of the Cyclecar Manufacturers' National Association was chronicled, as well as the definitions adopted by that association, by which an attempt was made to classify so-called cyclecars as cyclecars, light cars and small cars. It is somewhat surprising to learn that about the same time the automobile industry in Great Britain took steps to classify the machines of this type made in that country.

Classifying Various Types.

The American definitions place a car with motor of 70 cubic inches piston displacement and with weight of less than 750 pounds in the cyclecar class. Light cars have piston displacement of 70-100 cubic inches and weight of 750-950 pounds. A small car has piston displacement of 100-125 cubic inches and weight of 950-1150 pounds. It already has been pointed out, in these

columns, that additional confusion may result from the use in this manner of the terms light car and small car.

The British Definitions.

In Great Britain, the only attempt that has been made heretofore to define cyclecars was that of the Auto Cycle Union, which classified them solely for contest purposes as machines having motors of less than 1100 cubic centimeters piston displacement (approximately 66.7 cubic inches) and weighing less than six hundredweight (about 675 pounds). It is now proposed to amend this definition by substituting two: First, that a cyclecar shall be a machine with an engine not exceeding 1000 cc (about 60 cubic inches), and second, that a light car shall be a vehicle with an engine over 1000 cc and not exceeding 1500 cc (about 90 cubic inches). It will be noted that in these proposed classifications weight is not considered. The Autocar, one of the leading motoring prints in England, has

The World's First Cyclecar, the Bedelia, Produced by M. Barbeau of Paris, France, in 1910.

the following to say respecting the matter, editorially:

Motorists are more or less interested in the definition of the light car, for the simple reason that they never quite know what the term light car may mean; and the same remark applies to the term cyclecar. A car of nominally 15 horsepower, and with engine of approximately 3000 cc, may be correctly designated a light car, if it be light for its power and size, but the specialized, though far from general, acceptance of the term is that it describes a car with an engine of not exceeding about half this capacity.

The present confusion has arisen from the absence of a light car definition, and from the rapid development of the so-called cyclecar industry into what is nothing but a miniature or light car. It is true that very many purchasers of light cars or cyclecars do not care whether the machine is designated a cyclecar, a light car or a motor car, as they will call it a motor car whatever the Royal Automobile Club and the Auto Cycle Union may call it. On the other hand, so far as competitions are concerned, the confusion has been very great, and undoubtedly will be greater, unless a couple of practical definitions be established, and, besides, there is the inconvenience of not knowing what is meant by the two terms cyclecar and light car when so many people are using them quite naturally, to mean quite different things.

Many of the so-called cyclecar records on Brooklands have been made by light cars, with specially refined chassis to bring them inside the six hundredweight cyclecar weight limit. There is nothing to be said against

the special record or racing chassis as such; indeed, it is often the means of introducing meritorious modifications in the roadster chassis, but it is very misleading when the cutting of weight brings the racer into another class, as when it makes a cyclecar of a light car.

In making these favorable criticisms of the suggested definitions we should say we have no motives of self-interest to influence us, because we can dispense with the official definitions and use our own at any time if we wish to do so. Nevertheless, we confess we should prefer to see the present confusion of terms ended officially by a couple of common sense definitions, because their absence tends to misunderstanding and to bringing the governing bodies into disrepute.

TWO CHATAUQUA MODELS.

H. J. Newman's Concern Will Produce Passenger and Delivery Car Designs.

A short time ago it was announced that H. J. Newman, who has been connected with the industry for a number of years, had formed the Chautauqua Cyclecar Company at Jamestown, N. Y., on Lake Chautauqua, for the production of a

Chautauqua Passenger Model, with Side-by-Side Seating and Standard Automobile Tread.

cyclecar having wheelbase of 102 inches, standard tread (56 inches) and weight of 600 pounds. The concern is now ready to make detailed announcement of its product, which will be marketed in two models, one for two passengers, seated side by side, and the other for package delivery.

Despite the width of tread—for it is as yet somewhat impossible to disassociate the idea of a narrow tread with that of a cyclecar—this machine is a true cyclecar under the definition of the Cyclecar Manufacturers' National Association. The motor is a twin-cylinder DeLuxe special, air-cooled, with bore of 3.5 inches and stroke of 3.625. Lubrication is by splash, ignition by a Bosch high-tension magneto, and carburetion by a Schebler.

The transmission is by friction discs to the jackshaft, and thence by two V belts to the rear wheels. Although it is possible with a friction

transmission to secure any number of speeds forward or reverse, the design utilized in this machine is arranged to afford three forward speeds and one reverse. Both axles are of the tubular design. The service brake is contracting on the jackshaft, operated by pedal, while the emergency member is expanding on the rear wheels, actuated by a lever in the centre of the car.

The frame is of pressed steel, channel section, 2.5 inches deep, 1.5 inches wide and 12 gauge, well braced by transverse members. The front springs are quarter-elliptic and the rear, semi-elliptic. Wheels are of wire, fitted with 28 by 2.75-inch tires. The above applies to the passenger model, although the delivery wagon chassis is identical, save for the use of 28 by three-inch tires at the rear, and a reinforcement of the rear spring suspension to provide for heavier loads.

The body is of metal, finished in black enamel,

and the seats are roomy, with plenty of leg room—32 inches from dash to heel-board. One extra wire wheel is supplied. The lighting system comprises two electric searchlights, two side lights and a tail lamp. Current is supplied from a six-volt, six-ampere storage battery located under the seat. The maker claims that the

car is capable of a speed of about 40 miles an hour and a gasoline consumption of about 40 miles to the gallon.

WHO CONTROLS CONTESTS?

American Cyclecar Association Formed by Representatives of Local Clubs.

It appears that while the cyclecar manufacturers were busy forming their association at Chicago during the recent automobile show, representatives from the various local cyclecar clubs in Chicago, New York, Indianapolis, Detroit, Cleveland and other cities were organizing the American Cyclecar Association. Among other things, it is understood that this new body expected to take over the control of contest events for the new type of machine. However, the Cyclecar Manufacturers' National Association,

meeting for a second time shortly after the organization of the American Cyclecar Association, voted to co-operate in every way with the American Automobile Association. Since the American Automobile Association considers the cyclecar a motor car and has already granted sanctions for cyclecar contests, there appears to be some confusion on this score.

ANNOUNCES EUCLID MODEL.

Well Known Men Form Company for Its Production in New Haven, Conn.

Among the latest announcements in the cyclecar field is the Euclid, which will be produced by the Euclid Motor Car Company, with factory in New Haven, Conn., and general offices at 80 Broad street, New York City. The company is composed of a number of men well known in the industry, including E. S. Cameron, designer, who first began manufacturing automobiles in 1900; E. A. Scheu, general manager, who formerly was identified with the Packard Motor Car Company and was more recently general manager of the Invader Oil Company, and Frank S. Corlew, sales manager, who was until recently sales manager of Cameron Manufacturing Company.

The Euclid is officially described as a cycle-light car, being equipped with a four-cylinder motor of three-inch bore and 3.5-stroke. The wheelbase is 100 inches and the tread 40. The two passengers are seated side by side. The weight is about 775 pounds.

The motor is a C-S-C, air-cooled unit, made by the C-S-C Engine Company, and, like the car, is designed by Mr. Cameron. Ignition is by high-tension magneto, and lubrication by plunger pump. Power is transmitted through a sliding gearset of the progressive type, affording three forward speeds and reverse. The clutch is a cone. Final drive is by straight shaft with a single universal joint.

The front axle is a seamless, drawn steel tube, with drop forged ends. The rear axle is semi-floating. The service brake is external contracting, and the emergency, internal expanding, both acting on the rear wheel hubs. All springs are of the cantilever type, special design. The driver is placed at the left. The wheels are of wire,

fitted with 28 by three-inch tires all around.

It is understood that Mr. Corlew plans to leave New Haven, March 6, on a trip over the road to the Boston show, in one of these vehicles.

GENERAL CYCLECAR NEWS.

Brief Details Concerning Other New Models Announced Recently.

From New Orleans, La., comes the announcement of the Mino, made by the Mino Cyclecar Company of that city. Complete details are not yet ready for publication, but the designs call for a two-cylinder, air-cooled, V type motor rated at 9-15 horsepower. The gearset is a two-speed planetary type, and final drive is by V belts. The

Designer E. S. Cameron and Frank S. Corlew in Euclid Cycle-Light Car.

wheelbase is 96 inches and tread 36. The tires are 32 by three. This machine is to be equipped with an electric lighting and starting system.

Two more machines are announced from Chicago, these being the Standard made by the Standard Engineering Company, and the Steco, made by the Stephens Company. The former has wheelbase of 100 inches and tread of 42, and seats side by side. It utilizes a DeLuxe motor, friction transmission, single chain drive, wire wheels and 28 by 2.75-inch tires. The Steco is presented in three models, each of 100-inch wheelbase. One of these seats two passengers tandem, the second seats three and the third is a delivery wagon type. The motor is a two-cylinder, air-cooled unit with 70 cubic inches piston displacement. Power is transmitted by friction discs and V belts. The wire wheels have 28 by 2.75-inch tires.

DETAILS OF MARTELL ALIGNING REAMER.

A TOOL that was originally designed for the reaming of automobile crankshaft bearings, the idea being to provide the repair man

Martell Device Shown Aligned to Ream Crankshaft of Packard Motor.

with a means of accurately aligning these bearings and saving time in the operation, is the Martell aligning reamer, recently placed on the market by the Martell Motor Company, 1928 Columbus avenue, Boston, Mass. The simplicity of the device has suggested possibilities along other lines, but its practicability has been demonstrated in the service above mentioned, in that it is stated that it has been found that better results can be accomplished with three or four hours' work than with the same number of days by the old hand method.

The parts of the device are shown herewith. A is an eccentric, flanged bushing that, in use, is mounted directly on a shaft. U is a short shaft used in reaming connecting rods, but the longer shaft for reaming crankshaft bearings is similar in every respect, except for length. The flanged portion of this bushing is provided with a radial slot, concentric to the surface engaging with the bore of B, which is another eccentric, flanged bushing in the bore of which A is an easy wiring fit. The flanged portion of B is provided with six tapped holes, concentric with the bore, and a cap screw B₁, passing through the radial slot in A serves to lock the two bushings together in any desired position. The edges or faces of the flanges are graduated, A having 19 divisions and B 20, which give a vernier reading in thousandths of an inch, the extreme limits being 0 and .095.

C is a conical bushing, the tapered portion of which is provided with a fine thread, 70 to the inch, which permits it to be screwed very firmly into the ends of the bearings or holes to be

reamed. The bore of this bushing is ground to take the bushing B, and it is provided with four clamping screws to lock the position of B when the desired point is determined. The adjustable plug is shown assembled at V.

The reamer consists of two heads, D and E, carrying six blades in the slots, as shown in the assembly N. At either end of each of these slots are wedges S (enlarged) which engage the inclined surfaces of the blades I, J, K, and cause them to expand or contract as the adjusting nuts O, P, Q and R are moved in one direction or the other. T T are clamping nuts that hold the reamer head in any desired location on the shaft.

The other illustration presents the device aligned to ream the crankshaft of a Packard six-cylinder motor. This view shows the crankshaft gear mounted directly on the reamer shaft by means of a special bushing and the proper mesh of the gears is obtained by means of the eccentric bushings. The rear end of the shaft is then aligned to the clutch shaft bearing support at the extreme rear, and also aligned parallel to the top of the crankcase.

The blades of the reamer are made of non-shrinking steel, oil tempered, ground and provided with a six-degree cutting edge on the front end only. In order to ream clear through the bearing, the bushing at the back must be removed, when the reamer acts as its own guide for the short distance remaining to be reamed. The bushing is then returned to its former position.

When the reamer shaft is first lined up a positive turning movement is determined. Thus, if it be found that three ounces weight on a four-inch leverage will move the shaft, then, when the bushings are returned to their original positions,

Individual Components and Assemblies of Parts of Martell Aligning Reamer, Lettered for Convenience in Describing.

the same weight and leverage must produce the same result. In practise, however, it is said to be found necessary to use the weight but seldom.

The features of the device are held by the maker to be:

First, the supporting of the reamer shaft by a number of temporary bearings.

Second, the fact that these temporary bearings engage directly with the hole to be reamed, thus making the device entirely independent of any type or form of construction of the supporting members of holes to be reamed. The fact that the crankcase is not bolted down to a rigid base is an added assurance of perfection of alignment.

Third, the facility of adjustment of the position of the reamer shaft in relation to any point or points, as for instance, paralleling some given surface or obtaining the

correct mesh of a train of gears, one member of which is to be carried on the shaft for which the bearings are being reamed.

Fourth, the securing of a great range of adjustment of the reamer blades with a relatively small lateral movement of the adjustment nuts.

Fifth, the means of securing the reamer heads to the shaft in such a manner as to allow them to be solidly clamped in any desired position.

It is understood that the Martell reamer is to be demonstrated at the Boston show. The maker will supply full detailed information to those who are interested and make request.

GOODYEAR PRODUCING NEW RIM TYPES.

ANNOUNCEMENT is made by the Goodyear Tire & Rubber Company, Akron, O., of two new types of rims which are the result of more than a year of testing and experimentation to obtain an especially light, strong, effective quick detachable or demountable rim for No-Rim-Cut tires and all standard types other than clincher.

The new rim is made in the old Goodyear '07 profile, permitting the tires to widen out at the base and rest in their natural positions, the company pointing out that this construction provides greater air space and capacity, and makes for increased mileage. It is also held that the side walls are subjected to less stresses, as the beads are not pinched. In the new design the flanges are made high, and have the proper contour to give the necessary support to a No-Rim-Cut or straight side tire. Four styles are offered, these being shown in an accompanying illustration. The No-Rim-Cut detachable is a simple design, very light, averaging 10 pounds lighter than other types, effecting an economy of 40 pounds to the set. It will be noted that the base and inner flange have been combined in a single section with a groove in which the detachable flange is locked, while the separate locking ring has been eliminated, the outside flange being sprung into the groove in the same manner as the locking ring. It is supplied also in the demountable form.

In the demountable form the rim itself has the usual double-bevel seat, the inner side of which matches a corresponding bevel seat on the inside of the felloe band, while the outer bevel is supported by specially formed lugs, which are offset at an angle to correspond with a chamfer

on the outer edge of the band. Tightening a nut on the lug bolt serves to force the lug inward and upward over the chamfer, thus wedging and locking the rim into place.

The Ideal detachable is identical with the Goodyear '07 rim. Its side rings are supplied either for clincher or No-Rim-Cut tires as desired. It is heavier than the two-piece rim and is suitable for heavy cars. The rim is also supplied with demountable attachment when desired, attachment being made by means of a removable wedge ring fitting between the rim and

New Types of Goodyear Rims: A, Ideal Detachable; B, No-Rim-Cut Detachable; C, Ideal Detachable Demountable; D, No-Rim-Cut Detachable Demountable.

felloe band, and a set of lugs which serve to draw the wedge ring into place, thus providing the proper seating for the rim. All Goodyear rims fit standard Firestone and Kelsey felloe bands.

At the recent show of the Wisconsin Hardware Retail Association in Milwaukee, Wis., the Lippow Motorcycle Company exhibited a full line of Flying Merkel motorcycles, made by the Miami Cycle & Manufacturing Company, Middletown, O. Mr. Lippow, head of this concern, was assisted by William McKinley Sheets, central district manager for the Miami company.

ADVANTAGES OF POWER DRIVEN TIRE PUMPS.

Can Inflate Large Tires in One to Three Minutes, Economizing Time and Insuring Proper Pressure---Variety of Highly Perfected Designs Offered for 1914.

THE number of concerns engaged in the manufacture of power driven tire pumps has increased steadily during the past 12 months and, with those who have marketed designs for several years,

now form a branch of the au-

tomobile industry which is attracting attention both from the car designer and the owner.

The growing popularity of this equipment has been so simplified that it is possible to inflate designs. The present models are not only light in weight and very compact, but their operation has been so simplified that it is possible to inflate a large tire on the road in from one to three minutes, the time consumed depending upon type of pump. When it is considered that the operation involves no other labor than that of connecting the hose to the tire valve and moving a lever, the attitude of the public is readily understood.

Has Many Advantages.

The advantages are numerous when contrasted with the manually operated pump. It relieves the owner of arduous labor, is a great time saver, and, being fitted to the car, eliminates the possibility of being left in the garage or borrowed, as often is the case with the hand pump. More important than any of these is the matter of tire economy. It is a well known fact that the average motorist is prone to under-inflate his tires, and this is especially true when making a change on the road in hot weather. Frequently a lack of time is responsible for the improper inflation. By use of the power driven tire pump, with a safety valve, and a pressure gauge incorporated in the line, evils of guess work are eliminated.

Bastain Four-Cylinder Design.

That consideration is being given by the car designer to the fitting of the pump is noted in several 1914 models, and some makers who have not adopted the machine as stand-

ard equipment have made provision for its installation. Several instances are noted where the pump occupies a prominent position along with the dynamo and water pump, being driven from the same shaft.

Practical for Used Cars.

Many motorists desiring to equip their machines in this manner, have, in the past, decided that the work would involve a considerable expenditure and possible alterations to the power plant. Today it is possible for the owner of the used car to obtain all essential fittings, etc., and to install the pump at a moderate cost; in fact, several makers specialize in brackets, gears, pulleys, etc., for standard models.

Relative to the installation of the pump on the motor: It is generally a simple matter to attach a bracket for mounting the pump, and to take a drive from the shaft actuating the water

Assembly of No. 20 Four-Cylinder Universal Pump, Showing Clutch Mechanism.

pump and magneto, fitting a split gear to the shaft between these members. When this does not make for convenience a silent chain drive may be employed, or a gear fitted to universal joint housing, gearbox, etc. The majority of the manufacturers are prepared to submit drawings, indicating attachment, and specializing, as they do, apparent obstacles are easily overcome.

Highly Perfected Designs.

The modern types of power driven tire pumps are highly perfected little machines, and in the majority of instances are built along the lines of the automobile engines, having forged crankshafts, or eccentric shafts, pistons, and in many instances the connecting rods, patterned after those of the gasoline motor. The workmanship and material are first class in every respect, and the parts so assembled as to exclude foreign ele-

Kellogg with Gear Shifter.

the fours are cast en bloc, and in some cases it is noted that the upper half of the crankcase and cylinders are cast integral. The majority of the makers divide the crankcase much in the same manner as with the gasoline engine, utilizing the

ments and to be fool proof.

The designs include one, two, three and four-cylinder models, and in the casting of the cylinders motor car practise is followed; that is,

gines, are utilized, and it is stated that under the severest service the pumps do not overheat.

Cast iron is generally employed for cylinder material, with piston and rings of the

same metal, and the same care is taken in grinding and fitting as with the gasoline engine, as it is important, inasmuch as the compression is an

lower half for the oil reservoir, as splash lubrication is favored. In all models, precautions are taken to prevent the possibility of any oil being conveyed to the tire. While the vertical type predominates, there are some makes with horizontal cylinders; in fact, several machines are offered which are interesting because of the originality of their design.

Unlike the gasoline motor, the power driven tire pump is air-cooled, there apparently being no necessity of cooling by fluid. Flanges, very similar to fins utilized on the air-cooled types of internal combustion en-

important factor in the efficiency of the pump. Some makers incorporate eccentrics for the reciprocation of the pistons, while others make use of miniature crankshafts with the conventional design of crank throws. Not all are of the above named design, as one maker has attained success with a leather plunger piston, a type that is fitted to several 1914 models.

The speeds at which the pumps are driven vary. One maker states that his product will inflate a 36 by 4.5-inch tire to

Manzel with Clutch Shifter.

Manzel with Gear Shifter.

Tri-Phoon, a Three-Cylinder Type.

same manufacturer markets another model which at 700 revolutions a minute is said to be capable of inflating the same sized shoe in one minute and 30 seconds. Single-cylinder pumps may be obtained which will inflate a large shoe in from 2.5 to five minutes. There are several designs which are capable of inflating the largest shoe in three minutes, considerably less time than is required to remove the hand pump from the tool box or the tonneau.

In an accompanying table are given the dimensions of the leading manufacturers of power driven tire pumps, and the figures include the overall height, width, length, etc.

Tri-Phoon.

One of the most recent additions to the ranks of pump manufacturers is the Green & Swett Company, 737 Boylston street, Boston, which is marketing the Tri-Phoon, a three-cylinder design with several novel features. One of its qualities is that it is particularly adapted to used automobiles, the company specializing in brackets, fittings, etc., for standard makes of cars. The pump contains three reciprocating pistons driven by a rotary cam, the pistons being controlled on the cam surface by means of roller bearings, constructed of the best grade of steel, hardened and ground. Specially constructed metal piston rings are utilized. Simplicity, durability and efficiency are features of the design emphasized,

which is guaranteed and moderately priced. The maker states that at 800 revolutions a minute it will deliver a steady flow of pure, fresh air, equal to the pressure drawn from an air tank charged 115 pounds to the square inch. The

Tri-Phoon may be installed by means of a bracket and driven from the crankshaft, or the magneto, pump or camshaft. The pump proper is placed in service by means of a unique shifting lever or clutch. It comes complete with hose, gauge, etc.

Stewart-Warner.

The Stewart, made by the Stewart-Warner Speedometer Corporation, Chicago, is made in two models, a single-cylinder and a four. The design is similar to that of an automobile engine, with drop forged steel crankshaft, bearings, connecting rods, pistons, etc. The crankcase is divided and lubrication is by a non-fluid system. The connecting rods are driven by means of eccentrics working within the lower ring on the rod. The intake is valveless, air being admitted through apertures in the cylinder walls just below the piston head when the piston is in its lowest position. All working parts are fully protected from foreign elements. The single-cyl-

Colstad, Single-Cylinder, Designed Especially for Ford.

der design is constructed of the same high grade material, and both are noticeable for their compactness, light weight and efficiency. A clutch is employed.

Kellogg.

Kellogg pumps, made by the Kellogg Manufacturing Company, Rochester, N. Y., are four-cylinder units, and are made in air and water-cooled forms. The latter is more generally employed with motor starting systems. Each cylinder is provided with a double check valve. The pistons are actuated by eccentric cams placed on the shaft at angles of 90 degrees, a construction which the maker states insures a steady flow of air. The pistons are of a special anti-friction metal, made leak proof by a cup packing construction, and lubrication is by a splash system. Maximum efficiency is stated to be at 600 revolutions a minute, when it will inflate a 34 by four-inch tire to 75 pounds in less than two minutes.

Stewart Single-Cylinder with Shifter.

Drive is possible in a number of different locations. Connection with the driving member is by a clutch or gear.

Manzel.

The Manzel, made by the Manzel Bros. Company, Buffalo, N. Y., is a two-cylinder type and is constructed in several forms, these including a gearshifter style, plain and clutch. It is built along the lines of a gasoline engine and each piston is provided with two rings. All air is screened, and free from lubricant. Lubrication is by splash. Each model is equipped with a safety valve to prevent over-inflation, and it may be set at any desired pressure. This obviates the necessity of watching a gauge. At 600 revolutions a minute the Manzel will inflate a 36 by 4.5-inch shoe to 90 pounds pressure. In addition to the usual hose, etc., a coil is provided for cooling the air before it enters the tire. High

Stewart Four-Cylinder Design, Showing Construction Along the Lines of the Gasoline Engine.

grade material and workmanship are noticeable features of the designs.

The Colstad, produced by the Colstad Mechanical Laboratories, Atlantic, Mass., for which the Motor Supply Shop, 925 Boylston street, Boston, is distributor, is designed for the model T Ford car, and goes on the front end of the motor in place of the fan bracket. The pump is placed in action by moving a lever toward the dash, which meshes an eccentric with the fan pulley. It is stated that it is easily attached, will inflate a tire in three minutes, and is moderately priced.

Herz in Two Forms.

Herz & Co., 245 West 55th street, New York City, is marketing two types of pumps, one a friction driven and the other the B. B., a two-cylinder unit. The latter is very efficient and de-

velops a pressure of 250 pounds. Each cylinder has a separate intake and delivery valve contained within a housing which screws into the cylinder head. A safety valve is placed back of and between the exhaust valves, making it impossible to pump up more than a predetermined pressure. The B. B. is furnished with a clutch and so installed that it can be operated from the dash.

Peerless Driven by Chain.

Two models are produced by the Peerless Accessories Manufacturers, 1926 South Wabash avenue, Chicago—a four-cylinder and a special design for Ford cars. The latter is a single-cylinder unit driven from the engine shaft by an eccentric rod. The pump is placed in service by a rod outside the radiator. The stud holding the pump to the car frame is hollow and has a connection for the tubing carrying the air to the tire. The pump may be operated without stopping the motor or lifting the hood.

Designed for Ford.

The four-cylinder unit is practically the same as a gasoline engine, is mounted on a steel bracket, and is driven by silent chain. Ordinarily a sprocket on the magneto shaft is arranged to be engaged by a jaw clutch from the seat. The air is piped to a gauge on the dash, which has a connection for the tubing carrying the air to the tire.

The Universal Manufacturing Company, Minneapolis, Minn., is marketing a line of two and four-cylinder pumps, in which compactness and efficiency are emphasized. They are guaranteed to produce 300

pounds pressure. One of the several methods of installation provides for a gear drive and control from the driver's seat. Among other makers of high grade pumps is the General Utility Co., Philadelphia.

Master Two-Cylinder with Shifter.

SPARK PLUG POWER TIRE PUMPS.

SPARK plug tire pumps are not only moderately priced, but their use does not involve any other labor than that of fitting to the spark

Woodward Impulse Pump.

plug opening in the cylinder. Several makers provide quick detachable means whereby the spark plug core may be displaced by the fingers and the pump inserted and locked into position by a slight movement. Spark plug types of tire pumps are operated by the compression of the motor, and being very compact may be stored easily in the tool box. In all designs provision is made to prevent any lubricant being carried to the tire.

The Brown Impulse, manufactured by the Brown Company, Syracuse, N. Y., is of the quick detachable type, although early types were constructed to be screwed into the spark plug opening. Owners of these models may obtain the quick detachable connections at a moderate cost. The Brown is made like a motor, with two cast iron pistons and rings, and a connecting rod of high grade steel between the larger piston, on which the compression acts, and the smaller one which forces the air to the tire. The Brown is quickly placed in service and comes with ample length of tubing, gauge and connections.

The National Telescope pump, made by the National Motor Supply Company, Cleveland, O.,

Mayo Quick Detachable.

is a new design utilizing a floating piston having a tube attached to its upper side. As the piston in the engine cylinder moves up and down the compression and suction move the piston in the pump in a

like manner, causing the brass tube or piston stem to slide in and out at the top of the pump. The pump is but five inches high and the maker states it is very efficient, utilizing 100 per cent. of the area inside it. A feature is a neat wooden handle for tightening or loosening the pump in the cylinder. The usual tubing, gauge, etc., are supplied.

The maker of the Woodward Impulse pump, Woodward & Son, Toledo, O., claims a distinctive principle of operation.

It is termed a high momentive compound pump in that the power that operates it is due to the means by which the pressure is built up by the engine and released at a preconceived time. It is stated that a pressure of from 250 to 300 pounds is obtained with a 35-pound compression engine. The Woodward is guaranteed to 200 pounds pressure. It is equipped with insulated handles and comes with hose, gauge, etc.

The Mayo, made by the Mayo Manufacturing Company, Chicago, is now being marketed with quick detachable means, and the company is prepared to supply owners of former types with the new plug, which is made to fit early models.

Spark plug types of pumps are also made by the Garage Equipment Company, Milwaukee, Wis.; the Hill Pump Valve Company, Chicago; the Marvel Mfg. Co.

Brown Impulse Pump.

New Type of National Telescope Pump.

DASH PRIMER FOR MODEL T FORD MOTOR.

DESPITE the large number of moderately priced devices for assisting to start a cold motor, many owners display considerable ingenuity in fitting home made attachments. An instance of a practical installation was noted recently by the writer, and the owner stated that although the machine was stored in an unheated garage, it was an easy matter to start the motor in the coldest weather.

Fig. 1—Method of Shortening Top Straps.

The equipment is shown at Fig. 2, and comprises a dash priming cup, tubing connecting it with the intake manifold, and a spraying device, which is shown separate in the drawing. It will be noted that the last named member is perforated. The inventor attributes the success of the primer to these holes.

To utilize the primer a little gasoline is poured into the cup on the dash and the lever turned slightly to admit the fluid, also a little air. The fuel flows through the tube to the perforated member, and upon cranking the engine, the air drawn in through the carburetor and petcock breaks up the fuel, converting it into a rich mixture. It is stated that the motor will start on the second or third crank even in the coldest weather.

The material required to install the primer consists of a petcock, which is secured to a plate on the dash; a connector having a tubing and a pipe thread end, .125-inch annealed copper tubing, and a union. To the last named is soldered a piece of brass tubing which is drilled full of No. 62 drill holes. Its length should be approximately that of the diameter of the intake pipe into which it is inserted by drilling and tapping a hole. The manner of installing the parts is clearly depicted in the drawing. It is stated that the equipment described can be made at a slight cost.

The owner of the machine, which is a model T Ford, states that he has obtained increased mileage by the use of the primer, as the petcock on the dash may be opened to admit auxiliary air. In average running in warm weather he has secured 26.5 miles to the gallon, and 32 in

long trips. The car is utilized in business and in one season covered 13,000 miles.

FORD TOP HOLDER.

With the early model T Ford cars the top when up is held by straps running from the front to eyes on either side of the radiator. When lifting the hood, for example, the straps are in the way and to change their position, as well as to make for convenience when raising the top, the plan shown at Fig. 1 was devised by a reader.

With this model car the windshield is supported by rods extending from it to the forward end of the frame. Two clamps were made as shown in the smaller sketch, these being constructed of heavy brass and drilled to take a machine screw and locking nut. The eye for the top hook was inserted as illustrated and the clamps secured to the windshield rods so that when the top was raised and the straps were in position, the last named were in a vertical position. In the drawing they are shown at a slight angle to depict the method of attachment. The plan involves the shortening of the straps, which may be done at a slight expense, and the clamps can be made from the scrap heap.

LOCKING GREASE CUPS.

Grease cups, especially those in which a light lubricant is used, are sometimes lost through vibration. If it be found that the cup rotates too easily, or has a tendency to work loose, the fault may be corrected by compressing slightly the cup proper. A light tap with a small hammer will suffice. This will cause the cup to bind a little.

Fig. 2—Dash Priming Device for Ford Motor—The Fuel Is Broken Up by the Use of Perforated Tube Within the Intake Manifold.

FOX AUTOMATIC SWIVELLING HEADLIGHTS.

THERE were and are today motorists who favor the single dash swivelling headlight because its rays may be deflected to light up curves

Fig 1—Showing Anti-Dazzling Feature of Fox Lamps.

and to read sign boards. It has its disadvantages, however, in that to pick up and follow a curve, one hand must be taken from the steering wheel and the light skillfully operated. A design which provides automatic control of the headlights, permits of independent action of either, and does

not require new lamps or alteration of the regular members, is that of the Fox automatic swivelling headlights, manufactured by the Fox Auto Searchlight Company, 78 Fountain street, Providence, R. I.

The control of the headlights is such that when turning in either direction the lamps are turned in the same direction as the wheels, the turning movement of the lamps being at first much quicker than the wheels, decreasing gradually until the extreme position is reached. The rays of the inner lamp at direct ahead cover about 45 degrees of a circle, and these rays are swung about 45 degrees, so that they cover from a point at a right angle to the path of the car, while the rays from the outer lamp cover the path from a point directly ahead to the rays of the inner lamp, the two covering approximately a full quarter circle, so that all of the area from a point at a right angle to the path of the car to the point directly ahead of the outer lamp is illuminated.

When the car wheels are first moved by turning the steering wheel, the movement of the lamps is very rapid, the rays showing everything long before the car reaches it. The position of the lamps is not often the extreme, but the position covering the arc in which the car is turning is reached almost instantly, and when the wheels are set for a given position, either directly ahead or making a turn, the position of the lamps remains turned until the wheels are again moved.

The lamps illuminate curves and corners automatically, and in addition may be instantly controlled from the driver's seat independent of the steering gear, so as to throw the light across

curves or corners before reaching them, or if desired, to illuminate in this manner ruts, ditches, washouts or other obstructions by the side of the road. Another advantage is that the Fox light may be utilized to read sign boards, street names and house numbers. This feature will appeal to those who tour, etc.

One of the qualities of the construction is the elimination of the glaring effects. It is well known that it is the left hand lamp of the approaching car that is blinding. With the Fox design this lamp is deflected as shown at Fig. 1, lighting up the side of the road, while the other light projects its rays ahead. In traversing a road where one side is being torn up for repairs, etc., the outer lamp may be deflected to illuminate the obstructions and the rays of the other utilized directly ahead.

The equipment may be attached to any car, and one of its features is that the lamps are always automatically aligned. Lost motion of the steering gear does not affect their operation, as they are not actuated by the steering linkage, being independent of it. Adjustment is also provided, and the maker states that there is no wear of the parts.

The design is the invention of Joseph P. Fox, a pioneer in automobile construction, having had 15 years experience in France and Germany. For several years he was associated in experimental work with the late Otto Reimann, head of the well known German lamp firm of Reimann in Saxony.

John W. Coggshall of Rhode Island, well known in textile and financial circles, is president and treasurer of the Fox Auto Searchlight Com-

Fig. 2—Illustrating How Fox Automatic Searchlights Fully Illuminate Road and Curve—With Fixed Lamps the Inner Section Is Unlighted.

pany, George P. Patterson, connected with several business enterprises, general manager, and Mr. Fox, consulting engineer.

BOSCH ANNOUNCES LIGHTING SYSTEM.

AFTER considerable experimentation and tests the Bosch Magneto Company, New York City, is placing upon the market its electric lighting system for motor cars. Announcement was delayed until the engineers of the company were satisfied that the Bosch method of controlling the output of the dynamo was such as to prevent overcharging of the cells, and that the generator could be utilized to supply the current direct to the lamps.

The equipment is most complete, including as it does, the dynamo, switchboard, lamps, wiring, terminals, etc. One of the qualities of the design of the dynamo is that it closely follows the lines of the Bosch magneto; that is, the base plate is provided with dowel pins which register with the dowels of the generator. The plate is also provided with anchor straps. The height of the armature shaft from the base is such that it may be driven from the magneto coupling. One of the features of the mounting is that the holding strap is clamped by a single screw, permitting rapid dismounting.

The dynamo itself is of the shunt wound type, and the excitation of the field magnets is governed by an automatic controller of the electro-magnetic type carried in the switchboard. This controller reduces the strength of the field as the speed increases and conversely increases the field strength as the speed decreases, thus maintaining the output of the dynamo constant. The output of the dynamo is stated to be 12 volts, and its normal output 100 watts, or 7.5 amperes at 13.5 volts. This is attained at approximately 650 revolutions a minute. A test is cited in which, at an engine speed of 400 revolutions a minute the dynamo still generated, and between that speed and 3500 revolutions a minute the lamps could be switched on and off in any combination while receiving current directly from the dynamo without the use of the battery.

The Bosch dynamo is shown in an accompanying illustration with one of the brush gear covers displaced. This brush construction is retained by a single screw, and beside it will be noted one of the terminals of the type used throughout the system. These terminals are all interchangeable insofar as size is concerned, but

to prevent error in making connections, should the wiring be dismantled, each terminal is numbered to correspond with the number of its socket. These terminals are so arranged that the outer metallic casing of the cable forms the ground. It is stated that they cannot work loose or be over-tightened.

The switchboard is of novel construction. The dial of the instrument reads to right or left of zero, according to whether it shows "charge" or "discharge", and the switch is moved to one side to show voltage and to the other to indicate amperage, the same dial and calibration serving for both readings. The lower right hand switch is shown in the "off" position. D indicates that the current is switched direct to the lamps, B that the current is being run to the battery, and D B

Bosch Dynamo Lighting System: A, Terminals and Cables; B, Tail Light; C, Dash Light and Switch; D, Novel Switchboard and Meter; E, Dynamo; F, Brush Gear Cover Displaced to Show Terminal; G, Headlight.

indicates that the battery and dynamo are both in circuit. When the lower left hand switch is placed at "off", 1 indicates the side and tail lights on, 2 head, side and tail lights on, and 3 head and rear lamps on. The centre key is removable, and locks all the switches, which are of the kick type. This makes for convenience, in that the driver is not obliged to stoop when switching on the various combinations.

The lamp sockets are permanently focussed at the factory, and all bulbs are standardized, so that should a bulb be worn out it is necessary only to withdraw it and replace with a new one, when the focus will be found to be correct. The bulb is held in its socket by a spring contact plate in the back of the lamp and connected to the outside terminal. The headlight reflectors are carried in the body of the lamp, while the side light reflectors are in the front glass retainer.

The bulbs are held by bayonet holders. One of the qualities claimed for the headlights is that the light is cast in an exceptionally wide angle, thus illuminating hidden road constructions and curves of the road. In order to prevent unnecessary interference with the reflector the lamp is arranged so that the nut holding the bracket overlaps the screw of the latch.

The tail light shows a red and a white light, and the dash lamp is provided with a button

form of switch at its top for those who prefer not to have the light always on at night while driving.

One of the features of the Bosch system is that the dynamo is designed to be operated at engine speed. It may be driven by shaft, chain, etc., as best meets the conditions of installation, and is a separate unit, the Bosch company favoring this construction—one that is distinct from the magneto and starting units.

INAUGURATES NEW POLICY.

Bi-Motor Equipment Company to Conduct Wholesale Business Exclusively.

Although the Bi-Motor Equipment Company, Boston, Mass., decided upon its new policy of maintaining an exclusively wholesale accessory supply house on Jan. 1, the work of remodelling the store at 180 Massachusetts avenue was completed only recently. The concern is now in a

latter. The company was the first accessory house to locate on that street, but since its arrival the section has become a decidedly important factor in that end of the industry.

The concern carries all standard lines of accessories and supplies, and at present has eight travelling salesmen in the six states comprising the New England district. The decided increase in the number of garages and supply stores during the past few years has been the means of greatly augmenting the business of the company, and, in a large measure, impelled the decision to confine activities to the wholesale field.

R. S. Preble is president, and as he is also president of Excelsior General Supply Company, Chicago, and Manufacturers' Supply Company, Philadelphia, the concern has a working agreement with these two which has proved very satisfactory from the viewpoint of its customers. H. R. Curtiss is treasurer and R. M. Ellis is general manager.

The building at 180 Massachusetts avenue has been completely remodelled, and particular attention has been paid to facilities for filling orders and making shipments.

Home of Bi-Motor Equipment Company, 180 Massachusetts Avenue, Boston, First Exclusively Wholesale Accessory Dealer in New England.

position to meet the requirements of this trade, and it is maintained that it is the first accessory house in New England to adopt this policy.

The Bi-Motor Equipment Company was organized some six years ago, and started a wholesale and retail business on Portland street. Three men were placed in the field to cover the larger towns and cities of New England, and the success which attended the venture was particularly pleasing in every respect.

In October, 1912, it was deemed advisable to separate the wholesale and retail ends of the business, and a portion of the present quarters on Massachusetts avenue was acquired for the

AUTO THERMO-METER.

Stewart Radiator Device Indicates Temperature of Water Cooling System.

The Stewart-Warner Speedometer Corporation, Chicago, has brought out a thermostatic temperature indicator, termed the Stewart Auto Thermo-Meter, which is attached to the filler cap of the radiator and registers, by means of a hand passing over a calibrated dial, the temperature of the water cooling system.

One of the qualities of the design emphasized is that a thermostat is utilized and its bar is affected by the temperature of the air over the wa-

Stewart Auto Thermo-Meter.

ter. The heat or cold so actuates this bar that it moves a pointer over a calibrated, glass covered dial. The last named provides for readings from 30 to 212 degrees Fahrenheit, and it is stated that the figures may be read easily from the tonneau. It is also claimed that owing to the pointer hand moving over a curved dial, it is a simple matter to determine its position even when it is so dark that the Thermo-Meter can hardly be distinguished.

The function of the device is to enable the operator to note at a glance the operating conditions of the motor, as it is obvious that with too high a degree of temperature the indicating hand will warn the driver of trouble. Similarly, upon the cooling fluid attaining a temperature in the neighborhood of 32 degrees, the hand will indicate the need of attention to prevent freezing. The Stewart Auto Thermo-Meter is finished in brass or nickel and is moderately priced.

WHO WON SAVANNAH RACE?

Miami Cycle & Manufacturing Company Files Protest with Contest Chairman.

The Miami Cycle & Manufacturing Company, Middletown, O., maker of Flying Merkel motorcycles, has filed a protest with Chairman John L. Donovan of the competition committee of the Federation of American Motorcyclists, against the awarding of the 300-mile Grand Prize motorcycle race at Savannah, Ga., Dec. 27, to Robert Perry of Urbana, Ill., on an Excelsior. It is maintained that the real winner was Maldwyn Jones of Middletown, O., on a Flying Merkel.

Jones is said to have covered the first lap in 13:10, the second in 11:30, the third in 11:15, the fourth in 15:31, the fifth in 12:14 and the sixth in 11:15. After finishing the seventh lap he made his first stop at the pits for oil and gasoline, consuming but 53 seconds. The of-

ficial score shows that the seventh lap was covered in 24:30.

It is maintained by the Miami company that there was only one scorer to five riders, and that for some reason Jones was not cited on this seventh lap, but was required to make 28 laps of the course to Perry's 27. This view of the matter also is held by Mr. Ross, connected with the Indian agency in Cincinnati, O., who had charge of the Indian camp. L. G. Buckner, an Indian rider in the race, has filed a sworn affidavit with the Savannah Motorcycle Club that Jones, whose number was 19, started before him (Buckner), whose number was 38, and at no time in the race did he pass Jones, although Buckner is supposed to have been leading the race up to the 19th lap.

NEW ACCELERATOR PEDAL.

Hackney Design Is Ball Bearing, Simplifying Acceleration Control.

Leslie S. Hackney, St. Paul, Minn., inventor of the Hackney auto plow and designer of light farm tractors, has brought out a roller bearing accelerator pedal, which is shown in an accompanying illustration. It is attached to the regular pedal and permits perfect accelerator control.

Being ball bearing, any pressure applied to it results in an easy and gradual opening of the throttle, and with a minimum of effort upon the part of the driver. It also makes for economy of fuel in that friction is eliminated, which often results in too wide an opening of the throttle with some designs of accelerators. The device is very compact and is easily attached.

Hackney Roller Bearing Accelerator Pedal Simplifying Control.

Mr. Hackney has organized the Roller Bearing Pedal Company of which he is president and owner. General offices have been established in Hackney building, St. Paul, Minn.

NEWS OF THE MANUFACTURER AND DEALER.

The following concerns have been incorporated recently to manufacture or deal in motor vehicles, accessories, etc.:

Cataract Tire & Rubber Company, Providence, R. I.; \$20,000; general automobile and garage business; Clarence H. Broley, George Kirk, Elizabeth E. Broley, Mary Kirk.

Eastman Spring Company, Portland, Me.; \$500,000; to manufacture and deal in motor vehicle springs, etc.; E. V. Noble, E. V. Mann.

Osgood Automobile Deflector Company, Chicago, Ill.; \$50,000; to manufacture automobile accessories; S. W. Osgood, W. C. Kenner, J. J. Sheridan.

Benz Automobile Sales Corporation, New York City; \$25,000; general automobile and garage business; R. L. Enos, S. F. Enos, P. V. Clodio.

Brown & Robb Company, Gloucester City, N. J.; \$100,000; to manufacture automobiles; E. L. Brown, T. H. Robb, Herman Johnson.

Columbia Rubber Company, Boston, Mass.; \$50,000; Patrick H. Crowley, William F. Crowley, Hugh G. Cameron.

Hancock Engineering Company, Boston, Mass.; A. Schyler Clapp, William N. McKenna, John Sears McKenna.

Ceco Cycle Car Sales Company, Augusta, Me.; \$50,000; Ernest L. McLean, E. M. Leavitt.

Hercules Tire Protector Company, Boston, Mass.; \$10,000; John A. Gilbert, Elmer Balod, Adolph E. Elster.

Church Hydroplane Boat & Motor Company, Cambridge, Mass.; \$100,000; James E. Church, Hyman Pill, L. Levy.

Ontario Tire & Rubber Company, Inc., Buffalo, N. Y.; \$50,000; to deal in tires and rubber goods; H. V. Cook, F. L. Robinson, F. B. Rowley.

Keller Cyclecar Corporation, Wilmington, Del.; \$250,000; to manufacture cyclecars, motor trucks, airships, etc.; H. E. Latter, W. J. Maloney, O. J. Reichard.

Wilshire Auto Company, Los Angeles, Cal.; \$25,000; J. E. Price, Helen Smith, Walter Kerrick.

Allen Automobile Company, Evansville, Ind.; \$10,000; to conduct a general automobile business; C. A. Hughes, A. Underwood, G. C. Allen.

Manufacturers & Dealers Motor Underwriters, Inc., New York City; \$150,000; insurance, repair and reconstruct automobiles, etc.; E. Greenwood, W. E. Metzger, H. W. Henderson.

C. A. Coey Motor Company, Chicago, Ill.; \$50,000; to manufacture automobiles and accessories; C. A. Coey, H. L. Wells, H. H. Morgan.

E. & C. Auto Sales Company, Plainfield, N. J.; \$25,000; to do a general automobile business; F. Endress, E. A. Craig, L. A. Endress.

Levano Auto Supply Company of Houston, Houston, Tex.; \$20,000; H. M. Levano, M. Levano, J. L. Pujol.

Indiana Auto Supply Company, Laporte, Ind.; \$10,000; auto and repair business; Arthur Gaul, William Pelz, Alex Lindgren.

J. J. Laverty & Co., New Haven, Conn.; \$50,000; to deal in automobiles; John L. Laverty, Marie A. Wells, Frederick U. Wells.

Park Garage Company, Somerville, Mass.; \$10,000; Arthur N. Park, F. R. Curtis, W. W. Kennard.

H. Ross Maddocks Company, Boston, Mass.; \$25,000; to manufacture and deal in motor vehicles; H. R. Maddocks, Charles West, J. A. Maddocks.

Burgess Company, Marblehead, Mass.; \$100,000; to manufacture aeroplanes, boats, motors, etc.; W. Starling Burgess, Greeley S. Curtis, F. H. Russell.

Goodby-Rankin Company, Providence, R. I.; \$40,000; to manufacture accessories and supplies for automobiles, motorcycles and bicycles; also buying and selling automobiles, motorcycles and bicycles; Albert E. Goodby, William G. Rankin, Thomas P. Himes.

Park Square Motor Company, Pittsfield, Mass.; \$15,000; Fred K. Chaffee, Leslie M. Cain, Charles E. Jenks.

Cyclecar Distributing Company, Passaic, N. J.; \$60,000; hiring of cyclecars, auto vehicles, etc.; E. Huebner, G. Raradash, P. Miskovsky.

Victor Tire & Rubber Company, Camden, N. J.; \$125,000; to manufacture automobile tires, etc.; T. Skinner, H. V. Williams, E. P. Cropper.

Holl Motor Carriage Service Company, Camden, N. J.;

\$125,000; to manufacture automobiles, motorcycles, etc.; A. H. Holl, H. C. Henry, L. F. Holl.

Dayton Cycle Car Company, Joliet, Ill.; \$50,000; to manufacture and deal in automobiles; T. J. Moore, J. Storch, T. F. Donovan.

Standard Tractor Company, New York City; \$50,000; to manufacture and deal in motors, engines, tractors and machinery; J. W. Blaisdell, G. T. Whyte, D. H. Hamje.

Quick Change Storage Battery Company, Albany, N. Y.; \$500,000.

Auto Signalite Export Company, New York City; \$10,000; H. J. Woodsmith and others.

GARAGE AND DEALER.

The Pathfinder Motor Car Company, St. Louis, Mo., has taken over the building at 4160 Olive street, formerly occupied by the Cole Motor Company of Missouri. The company has a branch at 6417 Michigan avenue.

C. Baker, Cleveland, president of the American Ball Bearing Company, and formerly head of the Baker Motor Vehicle Company, is interested in a plan to establish a garage in that city, and the matter has been taken up with the Cleveland Automobile Club.

The Havers Motor Car Company, Port Huron, Mich., maker of Havers cars, has opened a sales branch at Detroit, on Woodward avenue.

The Apperson Bros. Auto Company, Kokomo, Ind., has opened a sales branch at Seattle, Wash., in charge of D. C. Gulehard.

The Firestone Tire & Rubber Company, Minneapolis, Minn., has moved into new and larger quarters at 1635 Hennepin avenue.

The Brasher Motor Car Company, Columbus, O., is having the building at the corner of Fourth and Gay streets remodelled for its use. U. D. Armstrong is general manager.

S. H. Stoneburner, Upper Sandusky, O., has purchased a half-interest in the Sawyer Motor Company and the name will be changed to the Upper Sandusky Overland Company.

The Moreland Motor Truck Company, San Francisco, Cal., has opened a factory branch at Fourth and Harrison streets.

V. A. Neilson has accepted the position of superintendent of the mechanical department of the Splittdorf & Apple Company, Chicago. For the past three years he has been associated with the New England branch of the Inter-State Automobile Company in Boston.

M. C. Hutte, Jacksonville, Fla., has opened a repair shop and garage in South Jacksonville.

The Kruse Motor Car Company, Cincinnati, O., will remove into its new and larger building at Eighth street and Broadway.

E. B. Sutton, Saginaw, Mich., formerly with the Belt Top Auto Company, is now engaged in the automobile business at 823 Genesee street.

The Calcasieu Motor Company, New Orleans, La., has purchased a new site and will erect a new brick garage to cost \$8000.

The Mangles-Kirby Company, Jacksonville, Fla., has leased the building at 17 East Church street, and will remove to that address at once.

James Mudge, Des Moines, Ia., is to open a new repair shop at 413 12th street.

Tauber & Tucker, Minneapolis, Minn., has opened a garage at 195 Western avenue.

Green's Purchasing Agency, New York City, distributor of Metz cars, has removed to new quarters at 62nd street and Central Park, West.

The Montauk Garage & Sales Company, Brooklyn, N. Y., agent for Jeffery, Pope-Hartford and Henderson cars, has moved into its new building at 1495 Bedford avenue.

The Mount Holly Garage, Mount Holly, N. J., has been sold to Sam P. Gokder and Horace C. Greems, who will continue the business.

The Leader Garage has been opened in Cumberland, Md.

D. L. Bennett & Son, Corning, Ark., is to erect a new garage on East Elm street. All modern machinery will be installed. The concern handles Ford cars.

Fred M. Case and **J. T. Stephens**, Hickman, Ky., have

formed a partnership and will engage in the automobile business. A new modern garage will be built.

The Prospect-Bulck Company, Akron, O., has opened a new garage at 216 East Market street.

The Motor Supply Shop, Columbus, O., has taken over the Motor Supply & Tire Company and is erecting a new four-story building at 128 East Gay street.

F. J. Dyett, Ilion, N. Y., has sold his garage to J. G. Stratton, who has taken possession.

J. S. Tony, Willows, Cal., has opened an automobile business at 429 West Oak street.

B. E. Terkelsen, Springfield, Mass., has opened a repair shop at 717 Main street.

The Ames Post Garage, Catskill, N. Y., is having plans prepared for the erection of an addition to its building on Church street. The concern handles the Cadillac and Overland cars.

The Webb Auto Company, San Angelo, Tex., has removed into the remodelled building on East Conche avenue.

W. R. Whitake, Marble Falls, Tex., has purchased an interest in the City garage. A new large building is to be erected.

The Chemi Company, Richmond, Va., which operates an automobile supply store, has opened a branch at Norfolk, Va., located at 723 Granby street. The company was incorporated last August.

H. W. C. Struebling, Sheboygan, Wis., who formerly operated a garage at 10th street and Michigan avenue, has purchased the August Prange garage on North Ninth street. Prange will remain with Struebling as salesman.

J. P. Wooten, Albine, Tex., has purchased the Majors garage on North Second street, and will conduct it under the name of J. P. Wooten & Son. The stock of accessories and supplies will be increased.

G. A. Lien, Columbus, Wis., has sold a half-interest in his garage and salesrooms to Fred Behncke and the firm hereafter will be known as Lien & Behncke. It is agent for Buick and Chalmers cars.

J. E. Cohagen, Hedrick, Ia., has taken over the garage business of R. T. McClain & Son at Fairfield, Ia. In his new location he will handle Buick, Studebaker and White cars.

Guy W. Campbell and his brother, C. W. Campbell, Waterloo, Ia., who conducted a motorcycle agency, have entered the automobile trade. They are now agents for Saxon cars.

J. R. Harris, Normal, Ill., has sold his half-interest in the Normal garage to his partner, P. E. Herr.

Lawton Ford Company is the name of a new firm in Lawton, Okla., in which E. W. Kirkpatrick and R. A. Parkinson are interested.

The Bee Automobile Company, Allentown, Penn., has been formed. It will be located at 17 North Church street and will make a specialty of body building.

Jerome Terwilliger & Son, Clinton, Wis., has opened a garage and salesrooms in the new Terwilliger building on Main street. A complete repair shop is connected with the garage.

Prothero & McGinnis, Baraboo, Wis., has leased the Dells garage in Kilbourn, Wis., and will conduct it in connection with the one at Baraboo.

WITH THE MANUFACTURERS.

The Oakes Pressed Steel Company, Indianapolis, Ind., maker of metal stampings of all descriptions, has found it necessary to remove into the enlarged plant at the corner of Division street and the Vandalia railroad, shown in the accompanying illustration. This action is the result of rapidly expanding business activities.

The Fisher Manufacturing Company, Lincoln, Neb., which manufactures the Rim-Grip sub-casing, a device designed to prolong the life of automobile tires, has announced its intention of erecting a second factory on the Pacific Coast. It is the purpose of the company eventually to invade the East, and locate a third plant in some centrally located city on the Atlantic seaboard.

The American Manufacturing Company, Lexington,

Tenn., has taken control of the manufacture of the Partin-Palmer motor car at the plant at Ecorse, Mich., recently operated by the Partin-Palmer Motor Car Company, Detroit.

The Dominion Motor Car Company, St. John, N. B., has leased property adjoining the Ford plant at Coldbrook, and will erect a large factory on the site for the manufacture of automobiles.

The New Haven Welding Company, New Haven, Conn., will enlarge its plant and thereby facilitate better handling of its products. The company is located at 67 Broadway.

The Golden West Motors Company, Sacramento, Cal., has the first unit of its large building completed, and the second unit will be ready in the early spring. That portion of the plant now ready for occupancy is 30x100, and the one being rushed to completion is 100x200.

McQuay & Norris, St. Louis, Mo., will soon move into its new factory, which is nearing completion. The company manufactures Leak-Proof piston rings.

The Perfex Company, Los Angeles, Cal., is now located in its new plant at Santa Fe avenue and 52nd street. The entire efforts of the company will henceforth be directed toward the production of a 1000-pound light delivery car for retail merchants. The new plant has a capacity of 30 cars a month.

The Willys-Overland Company, Toledo, O., has ordered payment by check to be made every week, instead of paying its employees twice a month, as heretofore. The National Bank of Commerce, of that city, has made arrangements to cash these checks with a special force

New Plant of the Oakes Pressed Steel Company, Indianapolis, Ind.

which will be kept on hand to pay out the \$125,000 of the weekly payroll. Before the new system was inaugurated the bank had to transport \$250,000 in cash, guarded by heavily armed policemen, every two weeks to the Overland plant.

The F. L. Moore Truck Company, Torrance, Cal., is now working to its fullest capacity, 125 men being employed. With the new machinery that has been installed it is expected that the output of the factory will approximate close to \$100,000 a month.

E. B. Gregg, New Castle, Penn., is said to have bought the plant of the Motor Car Company of that city. The property is valued at \$90,000. Mr. Gregg was formerly sales manager of this company and it is understood that he intends to operate the factory in a very short time.

A. C. Barley, Chicago, has purchased the factory of the Halladay Company at Streator, Ill., and is expected to resume the manufacture of the Halladay automobiles.

C. P. Kell, San Francisco, Cal., is interested in a large factory to be erected at Oakland, Cal., for the manufacture of commercial vehicles.

The Corsair Motor Company, Detroit, of which F. V. Whyland is the head, has secured office headquarters at 315 Free Press building. The company produces the Corsair motor, designed for the cycle and light car trade.

I. D. Rodecap, Detroit, who began in 1908 as production manager of the E-M-F Company and who for the last 2.5 years has been chief engineer, factory manager and purchasing agent of the Alpena Motor Car Company, has become production manager of the Lincoln Motor Car Company of that city.

TAKES OVER CARTER.

H. W. Johns-Manville Company to Handle This Make of Carburetor.

The H. W. Johns-Manville Company, New York City, which concern has taken over the sale and manufacturing control of a number of the best known motor car accessories marketed, announces that it has secured the Carter carburetor, manufactured by the Carter Carburetor Company, St. Louis, Mo.

The Carter differs from conventional forms of carburetors in that the supply of fuel is controlled by the suction of the piston of the motor instead of a mechanical device, and one of the qualities emphasized is its immediate response

Carter Carburetor, Having a Multiplicity of Jets, the Extreme Flexibility and Economy of Which Are Emphasized.

to the motor's demand when accelerating. This quick response is appreciated when traversing in crowded traffic. It is also stated that the supply is as quickly cut off when the throttle is closed, thereby saving fuel.

Economy of gasoline is claimed to be at least 30 per cent. by the method employed in breaking the fluid up into a fine mist. This is obtained by the use of a vertical multiple jet tube located in the funnel, and pierced with a number of small jets arranged spirally. As a vacuum is created by the motor, the fuel rises and falls instantaneously in the tube, according to engine speeds. Instead of being sucked through one or two jets, as in conventional practise, the gasoline emerges

through 16 openings. Owing to the size of the jets and the force with which the fluid emerges, the gasoline is broken up into minute particles and converted into a mist, which blends with the air, making a homogeneous mixture.

A feature of the Carter is the use of a by-pass priming device, which supplies a rich mixture for starting when the motor is cold. It is stated by the maker that it is possible to start on quarter-turns in very low temperatures.

Atmospheric changes are compensated for by means of a lever control, attached to the steering post. This lever is convenient to the driver and permits of regulating the supply of air. The Carter is said to provide flexibility and to make for economy, two important factors in operation.

COMING EVENTS.

March.

- March 2-4—Truck show, Cincinnati, O.
- March 2-6—Show, Fort Dodge, Ia.
- March 2-7—Show, Utica, N. Y.
- March 2-7—Show, Sioux City, Ia.
- March 3-6—Show, Grand Forks, N. D.
- March 4-7—Show, Cortland, N. Y.
- March 4-7—Show, Tiffin, O.
- March 5-7—Show, Elgin, Ill.
- March 7-14—Pleasure car show, Mechanics' building, Boston, Mass.
- March 7-14—Show, Hamilton, Ont.
- March 9-14—Show, Des Moines, Ia.
- March 17-21—Truck show, Mechanics' building, Boston, Mass.
- March 21-28—Show, St. John, N. B.

April.

- April 9-15—Show, Manchester, N. H.
- April 12—Show, Palermo, Italy.
- April 12-19—Show, Vienna, Austria.
- April 22—Track races, Bakersfield, Cal.

May.

- May 24-25—Targa Florio race, Italy.
- May 30—500-mile race, Indianapolis, Ind.
- May 30—Track meet, New York City.
- May 30—Track races, Providence, R. I.

June.

- June 6-7—Track meet, St. Louis, Mo.
- June 9-11—Isle of Man road race.
- June 17-18—Hill climb, Uniontown, Penn.
- June 30—Track races, Sioux City, Ia.

July.

- July 3-4—Road races, Tacoma, Wash.
- July 4—Track races, Providence, R. I.
- July 4—300-mile race, Sioux City, Ia.
- July 4—Grand Prix, Lyons, France.
- July 17-18—Speedway meet, Seattle, Wash.
- July 25-26—Grand Prix, Belgium.

August.

- Aug. 28-29—Road races, Elgin, Ill.

September.

- Sept. 5—Track races, Milwaukee, Wis.
- Sept. 7—Track races, Providence, R. I.
- Sept. 9—Speedway races, Pomona, Cal.
- Sept. 9—Road races, Corona, Cal.
- Sept. 9—Grand Prix, Italy.

October.

- Oct. 2-3—Track meet, Oklahoma City, Okla.
- Oct. 2-3—Track meet, Trenton, N. J.
- Oct. 4-10—International show, Berlin.
- Oct. 16-26—Automobile Salon, Paris.

November.

- Nov. 6-16—Olympia show, London.
- Nov. 8-11—Track meet, Shreveport, La.

Mr. Mileage Buyer:

You can buy cheaper tires but we don't make them.

Just so long as we put better materials into tires and give more careful attention to the manufacture, just so long we are going to ask a higher price. It costs more to make Republic tires because of the high class materials and superior workmanship but it is a Republic theory that the wise tire user is willing to pay the higher price when he receives the worth of his money. Republic tires are mileage tires—they give more miles per dollar. Hence they are the most economical in the end—one Republic tire sells another—Just ask a Republic user why.

Garage and Repairmen The Martell Aligning Reamer

Reamer in use on Packard "6" 1912. This job completed in 11 hours, including fitting connecting rods. How long would it take by hand, bearing in mind that absolute accuracy was maintained?

THE only device made by which a series of bearings may be perfectly aligned.

ADAPTABLE to any type or form of motor.

USE not restricted by any details of construction.

A high grade tool made from the finest of imported steel. A device that every up-to-date garage and repair shop should have.

Range of sizes from 1 5-8 inches to 2 1-4 inches. Send for catalog.

Martell Motor Company

1928 Columbus Avenue, Boston, Mass.

The Lincoln Highway Does not pass through my town

Why should I worry about the Lincoln Highway? I'd have to drive about 300 miles to get to it, and such a thing as devoting the time and money for a long tour is beyond me.

A Question:

Why should I contribute my little mite to this great Ten Million Dollar enterprise? I am not a sport. I am just an ordinary individual, clothing and feeding a moderate family and educating my children. By plugging hard six days in the week I am able to keep out of debt and keep money enough in the bank to buy a new tire occasionally. About the only diversion I have is romping with the kids and piling them and the good wife into the back of the machine and hiking out for a short ride in the country in the late afternoon. Dad is fortunate enough to own an old car and able to buy gasoline enough to keep it going.

The Answer:

Just the same, I am mighty glad if the little \$5 I can pinch out of my earnings will help make it a success. I expect to live several years yet, and I never expect to be without a motor car. I have been dreaming of the time when all our roads will be good, when I can drive 20 miles into the country without accumulating a bunch of expense for repairs. In a word, I want good roads and I want them so badly I can taste the desire. I know that when the Lincoln Highway is put through it will not be five years until every road of consequence in this broad land is a good road. It will spread a whole network of good roads. I will be personally benefited just as if it passed my door.

An Argument

Do you want cheaper hauling of farm products? Do you want a lower cost of vegetables, meats, everything that goes on your table? Do you want a more prosperous land to live in? If you want any of these things you want good roads, and in all the agitation for good roads there has been no movement that carries with it so much of promise for the immediate future as this Lincoln Highway.

Send your contribution to this patriotic cause TODAY to

J. M. The proved—
and approved—
Shock Absorber

The sign
of class

wherever cars run

And the assurance
of comfort.

No shock absorber has ever offered more definite, conclusive proofs of real service than we send for the asking. Simply write for the Ovington Data Chart "D", the eight simple lines of which—drawn by the car itself—tell the whole story.

No other shock absorber is so largely imitated. Trust the imitators to know what the public wants—or try to give them something that looks like it even if it fails to do the work.

Unity of Interest

The owners, the board of directors and the executive officers of the Pierce-Arrow Motor Car Company are one and the same group of men.

This means that the

PIERCE-ARROW

organization is one of united individuality, hampered by no outside interference or syndicated control. It means that the Pierce-Arrow directors are free to utilize their full resources of capital, brains and energy to the attainment of their ideal—the successful building and marketing of the best possible motor trucks and pleasure cars.

Every individual directly interested in Pierce-Arrow financial success is a working unit in the Pierce-Arrow organization.

The Pierce-Arrow Motor Car Company of Buffalo, N. Y.

KRIT

This is the Krit Special Touring Car, equipped with electric starter, 5 demountable wire wheels, Golde patent one-man top and seat covers. Complete, it sells for \$1150. Color, Napier green. No other car in the world near the price with so many new features.

A Few Thoughts to Guide You in Choosing Your Car

FALSE PRIDE USED TO PLAY a big part in the buying of a motor car. Price alone too often determined the selection. Folks wanted to be known as the owner of this car or that one because it cost a certain amount of money.

TODAY IT IS VALUE that guides the motorist. He looks for certain modern features in design, in appearance, in comfort, in appointments—and casts his verdict in favor of the car that possesses these and sells at the lowest possible price.

THE OWNER OF A 1914 KRIT GETS just as much motoring satisfaction and pleasure as the owner of a \$2000 or \$3500 automobile secures from his car. The KRIT sells for \$950. In appearance and mechanism it embodies accepted features to be found in the

highest priced cars—beautiful streamline body, tapered bonnet, rounded radiator, graceful fenders, electric lights, electric horn, electric starter, if you wish. It is complete to the last detail in the newest conveniences.

NOR IS KRIT ECONOMY confined only to the initial cost. For the new Krit is light in weight, and well balanced: thus, saving in gasoline and oil, and sparing on tires. ("The Text Book of Motor Car Economy" tells more—ask for it.)

SEE THE NEW KRIT AT the Boston Automobile Show. Observe its striking appearance. Examine its mechanism—evidence of clean engineering. Then you will understand why this car is meeting with popular acclaim everywhere—why it is declared to be two years ahead of its field.

Only 1 oil in 9 is correct for *your* car

Quality low
Body too thin
for your motor

Quality low
Body too thick
for your motor

Quality low
Body correct
for your motor

Quality medium
Body too thin
for your motor

Quality medium
Body too thick
for your motor

That is putting it roughly.

There are two vital factors in automobile motor lubrication. One is the oil's *quality*. The other is the fitness of the oil's *body* for your type of motor.

There are many variations in the *body* of oils. *Only one* is correct for *your* motor.

There are also many variations in *quality*. But, under the heat of service in your motor, only one *quality* will show maximum lubricating efficiency.

What if your oil is below the highest *quality* or incorrect in *body*? Loss of power or undue friction, or both are bound to result. Repair bills follow. Consumption of gasoline and oils mount up.

You may "want" correct lubrication. But you will seldom get it by chance. *It is now generally known that oil of correct body for your car can be determined only by detailed motor analysis—backed by scientific lubricating experience.*

The various grades of Gargoyle Mobiloils, purified to remove free carbon, are:

Gargoyle Mobiloil "A"
Gargoyle Mobiloil "B"
Gargoyle Mobiloil "E"
Gargoyle Mobiloil "Arctic"

Quality medium
Body correct
for your motor

Quality high
Body too thin
for your motor

Quality high
Body too thick
for your motor

Quality high
Body correct
for your motor

As a fundamental step in producing Gargoyle Mobiloils we analyzed the motors of every make of automobile.

Keeping before us the special requirements of gasoline engine lubrication we manufactured the several grades of Gargoyle Mobiloils from selected crude stocks.

In our lubricating chart, which will be sent any motorist on request, we specify the correct grade for each make of car.

Make note of the grade of Gargoyle Mobiloil specified for your car. Make sure that you secure it—buying preferably in the original barrels, half-barrels and sealed five-gallon and one-gallon cans, marked with the red Gargoyle.

On request we will mail a pamphlet on the Lubrication of Automobile Engines. It describes in detail the common engine troubles and gives their causes and remedies.

They can be secured from all reliable garages, automobile supply houses, hardware stores, and others who supply lubricants.

For information, kindly address any inquiry to our nearest office.

Immediate Start Greatly Increased Mileage
Greater Power, Greater Speed, Greater Hill Climbing
Ability If You Have a

Duelec Vaporizing Primer and Economizer

PRICE \$7.00

(Patent Applied For)

Attaches to intake manifold, at any location, in any position, operates from switch on dash. Half hour installs it.

OPERATION.

Turn on switch, give engine quarter turn, either by cranking, or by starting mechanism. A drachm of fuel (gasoline, kerosene, denatured alcohol, etc.,) is drawn from main feed line, enters heating chamber, is vaporized, inhaled by cylinder. The first spark explodes this HOT, FUMING, VAPORIZED charge. **YOU'RE OFF.**

The economizer begins operating as the engine speeds up. Feeding HOT air, resulting in great reduction of fuel consumption, vastly increased power and speed.

ADVANTAGES OF DUELEC.

No extra fount of gasoline, or risky mixtures required.

No incessant, tiresome, dangerous cranking.

No unnecessary, expensive spinning by self-starters.

No complicated mechanism. Works automatically.

SUPPLIES HOT, FUMING, VAPORIZED FUEL, for starting, and HOT air through economizer.

FORD OWNERS.

DUELEC operates from **MAGNETO**. Uses only 14 amperes. We will refund price, if it does not prove superior to any device to promote easy starting, and increase power with decrease of fuel consumption.

MOTORISTS. Demand **DUELEC** of your dealer, or we will send upon receipt of price, all fittings included. Great satisfaction guaranteed. 6, 8, or 12-volt battery supplies current.

DEALERS. **DUELEC'S** all round superiority, ease of installing, universal adaptation, and low price, makes it a **BEST SELLER**.

Starter, Engine, Cyclecar and Auto Manufacturers.

Send for **DUELEC**. We will submit one for trial and comparison.

Have your engineer test and compare with anything on the market.

Place your order accordingly. Patents allowed and pending.

Make remittance to order of U. S. Traub.

THE GREAT RIGHT WAY

TO STOP RADIATOR LEAKS.

Pour it in ~ now.
Finds the leak and
fixes it in 15
minutes.

SE-MENT-OL

Carry it in your car. It is always ready for use. No removing of radiator. No searching for trouble with torch and solder. SE-MENT-OL dissolves in the water. In passing thru the leak the cool air congeals it into a cement that effectually closes the cavity. Drain and refill radiator with fresh water.

IT'S A CINCH. ASK YOUR DEALER.

By the makers of CARBONOX which removes carbon at five cents a cylinder.

Bosch Spark Plugs

eliminate short circuits, breakage by accidental blow or heat and compression leakage, which are common faults often found in other spark plugs but never in Bosch Plugs.

Bosch Plugs are designed to uphold the reputation of the name they bear—they must be good.

Even the perfect Bosch Magneto cannot overcome the loss in efficiency resulting from the use of improperly designed and poorly constructed plugs. Don't use them—use Bosch Plugs.

Insist on Bosch Plugs and you can equal the spark plug efficiency of such high grade cars as the Peerless, Pierce-Arrow, Hudson, Mercer, Garford, Speedwell, Jeffery, Velie, Fiat, Marion, Case, Stutz, Moline-Knight, Lozier, etc.,—which regularly are Bosch-Plug-Equipt.

J. H. S. SHOCK ABSORBERS

are a revelation as well as a revolution in spring suspension.

Their sensitiveness of action **AUTOMATICALLY** takes up and destroys jars and jolts, either heavy or light, and to the occupant of a car it seems like riding on air—fairly floating through space.

Vibration is eliminated, thus giving long life to tires, motor, transmission and other components. In consequence greater speed is possible, as the car does not tend to skid or roll. The mechanical principle of the J. H. S. Shock Absorber is as scientific as that of a hydro-carbon engine. A cylinder and piston are used to insure durability, there being no fragile parts to wear or easily get out of order. The piston acts in harmony with coiled springs which destroy all shocks.

Keeton Car-Nation

Two Cars That Command Your Attention

The New Keeton Six is not ordinary in any sense of the word.

Distinction is written all over it.

The Keeton Six is a car that commands instant attention in any company—that stands out from the rest—a pleasing, powerful exponent of “class.”

In Keeton Sixes you secure a “foreign” car in all the essentials—as it ranks with the finest products of Europe in design, construction and finish, yet—its price is only about one-half that of an European car.

The mechanical features of the Keeton are of the highest order, based on sound engineering principles.

Keeton Specifications and Equipment

First, don't overlook the length—wheelbase of 136 inches—seats for seven and room for more—then the motor, six cylinders, 48 horsepower, very silent, most powerful.

Four speeds forward transmission, improved cooling system with radiator back of the hood instead of in front.

Electric starting and lighting, five interchangeable wire wheels, 4½-inch tires, power tire pump.

All these, together with the regular accessories, make the Keeton appeal to those who like distinction, combined with comfort.

Price F. O. B. Detroit, Keeton seven-passenger, \$3,250. Two-passenger body, if desired at same price, \$3,250.

The Car-Nation is Standard in every way and “The leader of the small car class.”

It has all the good qualities in style and performance of the high priced cars—yet has light weight and low initial and upkeep costs.

See that “V” shaped radiator, notice the strong wire wheels, also the streamline body—there is “class” enough for the most exacting.

It has “American snap” combined with a foreign appearance.

As a Car-Nation dealer you could fill your territory with “Car-Nations”—it appeals to people in all walks in life.

Car-Nation Roadster, \$495 Touring Car, \$520, As Catalogued

This “big little car” has a unit power plant, with 4-cylinder motor, large valves and bearings—silent and powerful.

The Car-Nation has three speeds forward and reverse, bevel gear drive with one universal joint; Hyatt Roller Bearings in rear axles.

Wire wheels, 30x3-inch, demountable, clincher tires, wheelbase 104 inches, horn, head and tail lamps with set of tools.

A card asking for our “Triple Test” booklet will be promptly answered.

\$485 The Salvador Cyclecar \$485

MOTORCAR VALUE AT CYCLECAR PRICE

PLAZA MODEL BOULEVARD-ROADSTER TYPE

Salvador has arrived a little late, but is moving fast in the streamline of quality.

The advent of The Salvador Cyclecar marks the finish of two years investigation of small car conditions in Europe and America.

The Salvador Car is designed by G. B. Mansur of Boston, who has been identified with manufacturing and selling of automobiles for 12 years. Mr. Mansur's association with The De Dion Bouton Co., of Paris, and his varied experience in American manufacturing, has enabled him to embody the best of European Cyclecar Models in The Salvador Cyclecar, to meet the practical requirements of the American Trade.

His beautiful Luxembourg exterior design in The Plaza Model meets every requirement of quality trade.

***Four Cylinder Water Cooled Engine,
Selective Transmission, Shaft-Driven
Car Is the Answer to Practical Cycle-
car Requirements.***

Salvador Specifications insure the owner the utmost in motoring combined with all the comforts and refinements of a high priced motor car.

NOTICE TO DEALERS

The Salvador Motor Co. plans a limited output for 1914. Absolute deliveries to begin April 10, 1914. Correspondence and bids for territory solicited. The Salvador Motor Co. gives an absolute guarantee covering material and workmanship on the Salvador Cyclecar.

SPECIFICATIONS.

MOTOR—4-cylinder, 4-cycle, 15 horsepower, water cooled, L head 70mmx100mm. Cast enbloc.

LUBRICATION—Self-contained, constant level splash and force system, plunger pump operated by camshaft.

COOLING—Water cooled, thermo-siphon system.

TRANSMISSION—Unit, with motor, crucible steel gears, double heat treated, oil hardened, running on ball bearings, three speeds forward, one reverse.

CLUTCH—Simple cone clutch, three-spring adjustable type.

FRONT AXLE—Tubular, with drop center, conventional type.

REAR AXLE—Bevel gear drive, patented non-skidding differential.

STEERING GEAR—Worm and sector type, with 15" steering wheel.

FRAME—Pressed steel, channel section.

SPRINGS—Front, ¼ elliptic; rear, cantilever.

WHEELS—Wire, 28x3 tires.

WHEEL BASE—100" wheelbase, 42" tread.

CONTROL—Left hand drive, center control.

GASOLINE—Gravity feed tank, located under cowl.

BODY—Luxembourg design: boulevard-roadster type, streamline effect; staggered seats with ample leg room; luxurious upholstery; parcel compartment in the rear.

SPEED—45 miles per hour. Plaza model, 65 miles per hour.

FINISH—Deep purple, black trimmings.

All We Can Ever Give

A chassis designed by R. E. Olds, as his final model—as the best he knew—after 25 years of car building.

A car built slowly, in a costly way, as though each car were built for Mr. Olds' own use.

A body of the coming type—a streamline body, believed in Europe to mark the limit in automobile beauty.

Equipment which includes, we think, all that motorists desire.

A price \$220 less than last year—now offering a value which, in all probability, no factory ever can excel.

Thus Reo the Fifth of this year fulfills all our ambitions—even all our dreams—after 27 years in this industry.

Now the Last Step—\$220 Saved

Reo the Fifth came out three years ago. Since then, the sole attention of our experts and designers has been given to its perfection. We have kept test cars running on the road, up to 10,000 miles per car. These cars are then taken apart and inspected. And every betterment which we suggested has been adopted in the chassis.

We have improved the finish and upholstery, the body design and equipment, until the whole car now measures up with the chassis. In none of these respects can we see any hope to do better.

have come from everywhere to inspect this model plant.

But we counted that investment final. Models thereafter were not to be changed. And we knew that sometime—when enormous output had repaid that investment—we could quote on this model a matchless price.

That time has come. This year we reduce our price 16 per cent. Last year's Reo the Fifth, completely equipped, sold for \$1,395. This year's price, with a better body and better equipment, is \$1,175.

Just as Costly

Yet the car is just as costly. save for lower prices on tires and electric starters.

It is still built of steel made to formula—steel analyzed twice. All parts must still pass the same radical

tests. All driving parts, as always, have 50 per cent. over-capacity.

There are 15 roller bearings, 190 drop forgings, a double-heated carburetor. Each car is built slowly and carefully. There are grindings and re-grindings, countless tests and inspections. And test cars are still run for thousands of miles to show up any possible weakness.

Each is built to run for years and years as well as it runs when new. To eliminate troubles, to minimize cost of upkeep. Many thousands of users now can tell you what such precautions mean.

Now Beautiful

And now the car is as handsome as a car can be. With a beautiful streamline body, deep upholstery, fine

finish. With electric starter and electric lights of the best type made. With integral windshield, with all modern equipment.

And with our exclusive one-rod control. No levers in the way of the driver. Gears shifted as easily as moving the spark lever—by moving a rod three inches.

Men who buy their cars to keep want a car like this. They want this finality, this staunchness, this up-to-date-ness. And they want, above all, an honest car, built in this careful, costly way. So many want it that our orders at times run five times our factory output.

We have dealers in a thousand towns. Name of nearest sent with catalog on request.

Two Radiator Shells Per Minute

THE above machine is another one of the numerous Overland cost reducers. This machine turns out 120 whole outside radiator shells per hour.

Small manufacturers, who must by necessity, use small equipment, can only turn out two per hour.

We make two per minute!

There you have the difference—which is one of the many rea-

sons why the Overland costs less than any other similar car in the world.

This machine cost \$12,500.00. It is 18 feet high, weighs 185,000 pounds, and has a capacity of 100 tons, or 200,000 pounds pressure.

It is called a "double toggle press" and is one of the most remarkable economizers used in the automobile business.

The Overland costs 30% less than any other similar car made. For catalogues please address Dept. 52.

BUY A TRI-PHOON AIR PUMP

The Day of the Back Breaking Hand Pump and the Troublesome, Unperfected Power Pump is Past. Today It Is All For Convenience, Pleasure and Practicability. The Price Brings It Within the Reach of Every Car Owner.

Features of the Tri-Phoon Car Pump

Simple—durable—small—light—and can be attached to any make of car. Highest efficiency—can be operated at any speed without injury to working parts. Will deliver at 800 revolutions a minute a steady flow of fresh air equal to the pressure from an air tank charged at 115 pounds to the square inch.

Brackets and fittings are furnished for attaching to all the latest models. Driven by rotary cam. No leather washers used. Lowest in price, complete with fittings and every pump guaranteed to be perfect. Will last a lifetime.

Size 6" Long, 4" High, 4" Wide.

Features of the Tri-Phoon Garage Pump

Delivered ready for instant use. Small and compact—takes but little room in garage. No pressure tank as tires are inflated direct from pump. Either direct or alternating current motors furnished. Can be attached to any plug. Mounted on neat truck with handle. All garage pumps are made for heavy service. All are guaranteed.

MERCER

AGAIN PROVES Its WONDERFUL ABILITY

FIRST IN GRAND PRIZE SECOND IN VANDERBILT

A Mercer, driven by Edwin Pullen, won the world-famous Grand Prize race at Santa Monica, Cal., Feb. 28, averaging 77.2 miles per hour for the entire distance, 404 miles.

At 300 miles the Mercer's average was slightly over 79 miles per hour—a new road record for the distance. The former Grand Prize record was broken, and a new world's record for 400 miles was established.

The second car to finish was 40 MINUTES behind the Mercer. The fourth car, Mercedes—one of Europe's best—was ONE HOUR behind.

An average of 77.2 miles means that the Mercer was travelling over 100 miles an hour on the straightaways.

In the Vanderbilt Cup Race, Feb. 26, a Mercer driven by Barney Oldfield, was second—only ONE MINUTE behind the Mercedes. The Mercer's average in this race—294 miles—was 75 miles per hour.

Had it not been for an unfortunate puncture on the 32d lap, which cost the Mercer slightly more than a minute, the result doubtless would have been different.

These remarkable victories again stamp the Mercer as being of superior construction. They were not achieved through any chance or luck, but were absolutely the result of merit.

The Mercer is not a one-time winner. For four years it has participated in speed contests of every description, being a consistent winner at all times.

This latest demonstration of Mercer endurance and efficiency should have great significance for the prospective buyer of an automobile.

Embodied in all Mercer models are the lessons we have learned from racing. Every car produced is built with the same regard for accuracy that made these victories possible.

Catalogue sent on request. Some desirable territory still open for live dealers.

"The Government insists that Railroads maintain fair and equal rates for all. Why should not manufacturers also have the right to maintain their prices?"

DETROIT, MICH. U.S.A.
October Seventeenth,
1913.

CPT-CB.

Mr. T. J. Daley, Sec'y,
Standard Woven Fabric Co.,
Framingham, Mass.

Dear Sir:-

On account of the satisfactory results obtained from tests of the Multi-bestos Arako Band Lining we have signed, and are enclosing herewith, our contract for 150,000 ft. which is our approximate requirements for one year.

Respectfully

Packard Motor Car Company,
C. F. Hollzger
Purchasing Manager

Why

The Chart shows the results of a series of tests conducted for us at the Worcester Polytechnic Institute to determine the relative superiority of Multibestos over five other leading brake linings. Just exactly how much superior Multibestos is in various braking qualifications is shown by the chart.

The figures from 0 to 36 represent units of pressure on the brake pedal. Figures from 0 to 100 represent the braking effect on the car wheel.

So, taking 16 units pressure, Multibestos shows a braking effect of 57; the other linings from 48 on down to 26 or from 85% down to 45% of the efficiency of Multibestos.

Insure the safety of the cars you sell by seeing that they are Multibestos equipped.

Immediate Deliveries

Mr. Dealer! Perhaps you are one of the hundreds of dealers who visited and admired the Vulcan display at the big Auto Shows this winter. Possibly you said :

"This is a splendid car. Your price of \$750 is right! It is the lowest price at which a man's size car can be made and made right. It is a car that will appeal to my customers—but can you make deliveries? If you can, it is the car I want to handle."

Now, Mr. Dealer—we want to set your mind at rest on the delivery point. **We are making car-load shipments daily.** We can and will fill any reasonable demand you make on us for this car. **And that goes.**

Two years of building and planning; two years of installing special machinery and making special tools were required to enable us to bring "The Vulcan 27" to its present high state of efficiency.

Quantity Production—is absolutely necessary in order to produce this car at the minimum of labor cost and at the same time to maintain the highest degree of perfection. This is the **only way** that the cost of production can be reduced to a point where it is possible to furnish this high grade car at a popular price.

Not an Assembled Car—The Vulcan is not an "Assembled Car." The building of the chassis complete (including axles, transmission, steering gear, clutch, etc.) and every part that enters into these various units is done in our own shops. We even build our own bodies. Our castings are

The Vulcan Mfg. Co.
Painesville, - Ohio

When Writing to Advertisers, Please Mention The Automobile Journal.

made in our own foundry. The sheet-metal work (for bodies, hoods and fenders) is done in our own shops by the most modern machinery, designed for economical production.

The "Vulcan" is so thoroughly standardized, every part so accurately made to gauge, that each part in one car will fit into every other car that we produce.

Throughout the entire chassis the most complete harmony is maintained. The result is that each little part in the "Vulcan" can be depended upon to perform its function in the finished car. Every part is as perfect as every other part. We realized that a single imperfect nut or screw would prevent basic harmony. That's why you'll find no files or reamers in the Vulcan assembling room. Everything slips into place with exact fit.

Rigid Inspection—No car leaves our factory until every individual part has demonstrated that it is perfect. It must be accurate to a fraction of one-thousandth part of an inch.

Quick Deliveries—We are in a position to meet and take care of a big consumer's demand for the "Vulcan 27" Speedster. Let us emphasize the fact that our ability to make immediate and continuous shipments means profit for you and satisfaction for your customers.

Greatest Value—Mr. Dealer, here are further facts that you cannot afford to overlook. When you deliver a "Vulcan 27" to a purchaser you are giving him 25% more real value for the money. Every buyer of a "Vulcan" is a "Booster" for the dealer who sold it to him.

For Live Dealers—We want a few more live-wire dealers to sell—not merely handle—the "Vulcan," as we have taken steps that will enable us to turn out a great many more of these cars this year than we anticipated.

We are only going to take on a few more dealers, as it is not a part of our policy to contract to deliver more cars than we can produce. Don't lose any time in getting our proposition. Write or wire today.

*Holds the World's Road Race Record
for 301-450 class—75.03 miles per
hour, former record 74.42*

Stutz Torpedo Roadster

Four cylinder—\$2000

Six cylinder—\$2250

Suit yourself about which model, but be sure it's a STUTZ

Stutz cars are sold to the "motor wise" who have their own ideas about which model to buy—a "four" or a "six."

We build both, and assume that you know what you want. We do not attempt to tell you which car is better *in theory*.

Stutz Fours and Sixes are built on identically the same chassis. The motors develop exactly the same horsepower. So, if you really appreciate high grade construction in a motor car, take your pick—a Stutz Four or Six?

The extra cost of a Stutz Six is only the extra cost of six-cylinder motor.

A Trustworthy Car

In performance, on track or boulevard, it is impossible to get a more trustworthy car than the "Sturdy Stutz."

Thousands of Stutz owners are finding that out. Power—Speed—Endurance—Freedom from mechanical trouble—these qualities make the Stutz the *Champion Road Car*.

Dealer's "Best Bet"

Last season we were unable to make contracts with any more dealers. We had just enough cars for those who had been with us from the first.

We are preparing to enlarge our field of operations and have a money-making proposition, based on merit, for the right dealers.

Write today for our proposition and Booklet No. A-5, Series E. Don't wait.

THE AUTOMOBILE JOURNAL

VOL. XXXVII, No. 3

MARCH 10, 1914

Price, \$1.00 the Year

BOSTON SHOW AGAIN SETS NEW RECORDS.

Crowds in Attendance, Increase in Sales and Number of Agency Contracts Demonstrate Importance of New England Market—Artistic Decorative Treatment.

ALL attendance records for the Boston automobile show were exceeded early Friday morning. Over 240,000 people had visited the big display when the doors were closed Thursday evening. The previous record was made in 1913, when 245,000 admission tickets were counted by the attendants at the doors. Of course, these figures do not include the employees of the various exhibitors admitted on season passes, but represent those persons actually interested in the vehicles and accessories on exhibition.

And it was particularly noticeable this year that the crowds began to appear during the early morning hours, many people being in line each day waiting for the doors to open.

While it is still too early to make a definite statement regarding the sales consummated during the week, it seems safe to predict that a new record will be created here, as well. The Boston automobile show always has been the retail selling exhibition of the year, and in 1913 it was estimated that the total sales amounted to over \$2,000,000.

Indicating the Remarkable Beauty of the Decorative Scheme for the Twelfth Annual Boston Automobile Show—The Main Feature of the Venetian Setting on the Stage of Grand Hall.

Partial View of Accessory Division in Balcony of Exhibition Hall, Showing One of the Side Aisles.

It has been true of every automobile show held this year, that surprises have been experienced by the exhibitors, and in this respect the Boston show is no exception. While the retail sales have more than held their own, according to statements made by the exhibitors throughout the week, there has been by far a larger number of dealer's contracts signed than ever before at a display held in this city.

Still the Biggest Show.

This is a particularly surprising situation, since the Boston show is a dealer's proposition, conducted by the dealers of Boston, and while they have every assistance from the manufacturers, officials of the company have not hitherto regarded it as an especially fruitful field for securing new agencies. These usually are signed up, insofar as the East is concerned, at the New York show. Of course, it always has been true that dealer's contracts have been closed during Boston show week, but the number this year was such as to occasion much comment among factory men present.

The Boston automobile show still retains its position as the largest in the world. A careful count of the machines on view indicates a total of 106 different makes—82 gasoline automobiles, eight electric, one steam and 14 cycle-cars—and 318 complete cars and chassis. Of these, 25 makes were shown in Grand hall, 35 in Exhibition hall, 43 in the basement and three in the balcony. Last year there were 108 different makes and

323 cars and chassis, but it will be understood that several concerns making display in 1913 are no longer producing cars, either through withdrawal from the industry or because of consolidations with other companies.

Comparison may be made with the 1914 shows in New York and Chicago. In the former city there were 78 different makes of machines and 318 complete ve-

hicles and chassis, so that it will be seen that while there was a lesser number of makes, the average of cars displayed by each was such as to bring the total exhibits to same figure shown in Boston. In Chicago there were 86 different makes on display and a total of 302 cars and chassis.

In order to make comparison with foreign shows, it is necessary to add the truck exhibitors, since trucks and pleasure cars are shown together in Paris and London. At present there are 35 different makes of trucks and business wagons scheduled for the second week of the Boston show, which, added to the total of 106 for the pleasure car section, makes a grand total of 141. Paris had 132 and London 126. It is expected that the list of truck exhibitors will be increased materially during the last few days preceding the opening of the display. Boston has

Looking Down the Main Aisle in Exhibition Hall, Where Cars Were Displayed in an Old Roman Setting.

every right to the title, "Greatest Automobile Show on Earth".

It has seemed each year that Manager Chester I. Campbell and his brother, Architect Ernest W. Campbell, had exhausted every opportunity to produce a more pleasing spectacle, yet the decorative scheme this year was even grander and more artistic than ever before. No part of the building was neglected. Even in the basement, where it is conceded to be a difficult matter to devise satisfactory means for disguising the somewhat unattractive interior, handsome oil paintings covered the side walls and bunting was utilized elsewhere to secure a most pleasing effect.

Upon entering Mechanics' building at Huntington avenue and Exeter street, the corridor leading to Exhibition hall was found to be converted into a triumphal archway, reminiscent of the old Roman period, flanked on either side by pilasters and marbleized work to create the impression of stone walls supporting the arches. This treatment was continued within Exposition hall itself, the effect being that of a Roman festival.

The wooden posts supporting the upper floors were treated with marbleized board, representing pillars, on top of which were grouped Roman banners in bright colors, each group being sur-

Arrangement of Accessory Booths on Second Floor of Exhibition Hall, and Decorative Scheme Employed.

mounted with the Roman battle shield bearing the letters S. P. Q. R., signifying Senatus Populusque Romanus—the Senate and the Roman people. The light well in the centre of the hall was treated to represent a court yard in a large Roman house, the marbleized front producing the effect of house walls, relieved by bright awnings. The side walls were decorated with paintings, flanked by marbleized work, and flowers were used profusely to relieve the otherwise stately effect of the banners. The exhibition spaces were set off by pillars surmounted by illuminated glass balls, bearing the name of the car.

Venetian Setting in Grand Hall.

It is in Grand hall that the decorator usually seeks to exert his greatest skill, and the effect this year was such as to cause instant appreciation. Photographs failed to do justice to its exceptional beauty, because the camera utterly fails to reproduce the rich colorings employed. It is almost as futile to attempt to describe the impression created.

The scene reproduced was that of Venice as approached from the sea, with St. Mark's and the Ducal Palace near at hand. The oil paintings on the stage and along the side walls, above the balconies, were arranged to present the fronts of houses and to give the impression that the visitor was sailing along the Grand Canal. Apparently, the city was dressed as for a gala occasion, with a liberal use of banners in the brightest of red and gold. Venetian crests and marble lions were so placed as to

General View in Grand Hall, Showing Pleasure Cars Amid Surroundings Depicting the Grand Canal, Venice.

Handsome Treatment of Stairways Leading from Exhibition Hall to Accessory Section on Upper Floor.

increase the illusion, and the exhibition spaces were marked with high poles, such as are utilized in the Grand Canal for mooring gondolas, surmounted by red and gold banners bearing the name of the car. High above all was a mosaic painting, representing the sky, dependent from which hung eight electroliers, each composed of 12 Venetian wrought iron lamps. The effect at night was particularly pleasing.

The Venetian setting was continued in the balconies on Grand hall, of course, but in the balconies and upper rooms over Exhibition hall, paintings, floral decorations and bunting were utilized to transform this section of the display as never before. Mention already has been made of the basement.

Cars were shown in Exhibition hall, Grand hall, the basement, and for the first time, in the balcony of Grand hall. In the basement, also were to be found the largest exhibition of cyclecars yet held in America, a representative display of motorcycles and a number of accessories, supplies and fittings. The main accessory showing was in the balconies, however, as in past years.

Insofar as the cars were concerned, of course the display was the most complete

ever held, and while many machines were exhibited at Chicago which were not seen at New York, there were several makes which had not been seen at a show of national prominence during the 1914 season. Among these were the Ford, Inter-State, Knox, Lenox and Moyer gasoline cars; Bailey and Buffalo electrics and Stanley steam. The Renault might be included, although this make was shown in connection with the Importers' Salon in New York.

New Cars on Display.

The Ford was presented in the touring car, runabout and town car, and with none of these has there been any decided change in design or construction. The Inter-State was represented by the model 45, which is the six-cylinder car announced for the 1914 season by the old Inter-State Automobile Company, before the purchase of the concern by the new Inter-State Motor Company. The new car, recently announced by this company, was not completed in time.

Knox cars were shown in four and six-cylinder models, as touring, roadster and enclosed types, the latter being with the natural wood finish, for which this make of machine has been noted in recent years. The Lenox line also comprised four and six-cylinder machines, fitted with touring and roadster bodies, and an entirely new speedster design with pointed radiator and other distinctive features. The Moyer was presented as a six-cylinder touring car and a four-cylinder roadster. The details of all these lines, as well as of the Stanley steam cars, were presented in the last issue of *The Automobile Journal*.

The Bailey electric was displayed in the enclosed type, as well as in the two and four-passenger roadsters. The last named was first seen

A Detail of the Decorative Scheme in Grand Hall—An Extension of the Grand Canal Over the Balcony at the Rear.

at the electric show in New York City last fall, and has occasioned some little interest because of its appearance, which is not unlike that of the four-passenger gasoline machine. The Buffalo electric was shown in two enclosed types, one of which was with bare aluminum body, giving full opportunity to inspect the material before it had been painted.

As forecasted in the last issue, there were several cars seen in Boston for the first time, these being the Allen, Chandler, Car-Nation, Howard, Briscoe, Keeton, Willys-Knight, Saxon, Moline-Knight, King, Herff-Brooks and Lyons-Knight. The new models of

Space Occupied by White Cars, Indicating Attractive Appearance of the Individual Exhibits in Grand Hall.

of horsepower. Several new body designs were shown on other machines, these following so-called conventional lines for the most part, with the exception of that fitted to the KisselKar 4-40. With this there is but one door on either side, entrance to the front being by way of the tonneau, there being a passage way between the individual seats. As has been true in other years, there were a number of handsomely appointed enclosed bodies.

The Accessory Display.

Special reference is made elsewhere to features of design and construction, and also to the cyclecar division of the show, which was a distinctly important factor. Nine makes of motorcycles were shown in the basement, these being the Flying Merkel, Excelsior, Indian, Jefferson, Harley-Davidson, Henderson, Pope, Thor and Yale.

It is somewhat difficult to make comparison between the showing of accessories, supplies and fittings this year and that of previous displays, for the reason that these lines were presented

One of the Individual Accessory Booths: H. W. Johnson-Manville Company, Near Light Well to Exhibition Hall.

cars otherwise well known in Boston included the following: National Six, Jeffery Six, Lozier Four, Packard 4-48, Premier Weidely, Chevrolet Baby Grand and Royal Mail, Maxwell 25-4 and 35-4, Mercer O and M, Pathfinder Leather Stocking, Hudson 6-40, Velie 6-50, Abbott-Detroit Belle Isle, Henderson Six, Marion G, Haynes 27, Maxwell 50-6, Buick B 55, Imperial 44 and Apperson 6-45.

The Packard 4-48 is an entirely new model, announced since the Chicago show, and therefore shown for the first time anywhere. It does not depart greatly from the 2-38, announced previous to the New York show and displayed at that exhibition, except in the matter

Display of Overland Cars Sets Forth in More Detail the Arrangement of Old Roman Banners, Etc., in Exhibition Hall.

Attractive Display of Acco Lubricants and Salesmen in Attendance at A. C. C. Oil Company's Booth.

very largely by local dealers instead of by the manufacturers themselves. Early in the season the Motor & Accessory Manufacturers decided not to issue a sanction for this show, thereby prohibiting its members from making display direct. Efforts were made to have this decision reversed, but without avail.

New Lines Revealed.

Despite this serious handicap, the accessory division of the show was even more representative of the industry than ever before, although individual lines were grouped in the display made by the local dealer or distributor and failed to make the same impression that they would have done had it been possible to follow the custom of past years. The showing of tires was more general than at either the New York or Chicago exhibitions.

Many new lines were revealed; that is, many new lines were displayed for the first time at any automobile show, although practically all of these were more or less well known to motorists

who have followed the New Accessory department in The Automobile Journal. Those who sought to dismiss this section with a cursory examination were surprised to find the extent of the lines allied with the automobile industry, the display including practically everything that could be desired for the comfort and convenience of the motorist, or for the economy of maintenance and operation of the car.

Among the products not seen hitherto were the following: Calnan tire tool, made by James P. Calnan, West Upton, Mass.; Cochran Speednut wrench,

Where Prowodnick Tires Were Shown by Columb Tyres Import Company.

Cochran Pipe Wrench Manufacturing Company, Chicago; Lawrence motor lock, for locking the emergency brake lever, Lawrence Specialty Company, Dorchester, Mass.; Lewis mechanical gearshift, Lewis Manufacturing Company, Philadelphia; Merrimac enclosed door hinges, Merrimac Hinge Company, Merimac, Mass.; Thumlock pipe coupling, Gurnard Manufacturing Company, Beverly, Mass.; Webber carburetor, Webber & Blomquist, Neponset, Mass., and Two-Way valve tool, L. D. Robbins Company, Lynn, Mass.

The 1914 Boston automobile show will go down in the history of the automobile industry as the most complete showing of its products ever made in this country or abroad. It has established

Houk Wire Wheels Were Shown by George W. Houk Company in the Balcony of Grand Hall.

new records in both attendance and sales, and has again demonstrated that New England is the greatest motor vehicle market in the world. It is a fitting climax to the 1914 show season, and manufacturers and dealers will enter the active selling period satisfied that the optimistic view of the situation made public by Boston dealers early in the winter was well founded.

UTICA'S ANNUAL SHOW.

Twenty-Eight Makes of Cars Displayed Amid Surroundings of Green and White.

Twenty-one members of the Utica Automobile Dealers' Association exhibited 28 makes of cars at the annual show in the state armory, Utica, N. Y., March 2-7, under the auspices of the Utica Automobile Club and the management of W. G. Comstock. Some 18 dealers in accessories also were represented. The setting was green and white, and, as indicated by the accompanying illustration, the effect was decidedly pleasing. Those who displayed cars were:

Utica Saxon Motor Company, Saxon; H. W. Skinner Motor Car Company, Packard, Chandler; Daiker Motor Sales Company, Maxwell, Winton; King Motor Agency, King; Chas. H. Childs Company, Jackson; Frank E. Henabray Motor Company, Oakland; I. R. Gardinier, Empire, Pullman; H. D. Crim Automobile Company, Studebaker, Cole; Robert F. Payne, Velle; Beatty-Buick Sales Company, Buick; Utica Motor Car Company, Cadillac; Otis Motor Sales Company, Reo, Ford; Fiscus & Harris, Auburn; John M. Weaver, National, Stutz; Regal Agency, Regal; Schiller & Creswell, Detroit electric; Franklin Motor Car Company, Franklin; Geo. M. Redding, Allen, Haynes; Metz Motor Sales Company, Metz; Stevens-Duryea Company, Stevens-Duryea.

TAKES OVER DEAN BUSINESS.

Garford Manufacturing Company Is Being Organized for This Purpose.

According to information from Elyria, O., the sale of all property, assets, patents and good will of the Dean Electric Company of that city has been made to A. L. Garford, who is organizing the Garford Manufacturing Company with capital of \$500,000 preferred and \$800,000 common to take over the business. The proposition submitted by Mr. Garford provided for the exchange of preferred stock of the Garford Manufacturing Company for bonds of the Dean Electric Company, which were outstanding, amounting to

\$250,000; all creditors' claims, totalling \$427,000, to be put in the form of notes and assumed by the Garford company to be liquidated over a period of five years.

The officers of the new company are: President, A. L. Garford; vice president and general manager, A. G. Bean; directors, A. L. Garford, president, Cleveland Automatic Machine Company, Cleveland, O.; John Sherwin, president, First National Bank and First Trust & Savings Company, Cleveland; H. H. Johnson, M. B. & H. H. Johnson, Cleveland, attorney; A. G. Bean; A. L. Patrick, certified public accountant, Cleveland; John P. Brophy, vice president and general manager, Cleveland Automatic Machine Company, and E. F. Allen, president, American Lace Company, Elyria.

It is stated that the new company will continue the production of telephones, switchboards

Company, Metz; Stevens-Duryea

and electrical apparatus, and that it will largely increase the automobile accessories department. This includes electric horns, speedometers, lighting generators and motor starters.

MOSLER FACTORY SOLD.

Street Improvements Necessitate Erection of New Plant in Another Location.

Announcement is made from New York City that the factory of A. R. Mosler & Co., Mount Vernon, N. Y., maker of Spit Fire Spark plugs, has been sold to the Bronx Parkway Commission for \$93,000. It is understood that this property will be utilized for an extension of a boulevard to Kensico. It is further stated that two new factories will be erected by the Mosler concern within six months, but the site has not been chosen.

DETAILED REFINEMENTS OF 1914 MODELS.

What the Manufacturer Is Providing in Comfort and Conveniences—Improvements in Mechanical Construction—Factors That Appeal to Prospective Purchasers.

WITH Boston the final word in the 1914 show season, the motor car manufacturer retires in favor of the sales organization. The most critical observer cannot but concede that there is decidedly more value offered the prospective purchaser than formerly, and that tempting inducements are held forth even to the owner of a 1913 model to change for the newer design. And in these days of the perfected automobile, insofar as the mechanical construction is involved, the maker must provide conveniences and comforts not existent in former models if he would appeal to the owner of a modern machine.

While the conservative owner held that the general adoption of electric lighting and motor starting in 1913 was the last word in equipment, the show season just closed demonstrated that the car manufacturer, body builder and equipment and accessory maker, have again displayed their ingenuity in producing features that appeal to even those not contemplating the purchase of a new model.

To the casual observer it would appear that only small

details have been refined; that the manufacturer has made his product more attractive to the eye.

While this holds true in some respects, those who have followed the development of the automobile industry as exemplified by the annual displays, find a wealth of details which not only contribute to the pleasures of motoring, but eliminate discomforts formerly existing. Viewed from an artistic standpoint, a study of the bodies offered shows that immense strides have been made during the past 12 months. The streamline formation of the car body as a whole, that was just beginning to make itself evident at the shows last season, now has become the rule. Wherever bodies have been redesigned there is a marked tendency toward the long, smooth flowing lines, and in practically every instance it has resulted in much improvement esthetically, while the more practical, but no less important, aspect of comfort has not been overlooked.

A noticeable development in body designs this year is the double-purpose type, which is adapted to be transformed easily from the open

The Streamline Form of Body Is Now Standard Practice Not Only in the Higher Priced Cars and Limousines, but in the Popular Priced Types.

to the enclosed. This tendency predominates mostly in cars of smaller seating capacity, practically all of the development along this line being in the combination of the coupe and roadster or runabout. These combinations appear under different names, such as landaulet-coupe, cabriolet, coupelet, coupe-roadster, landau-roadster, convertible, all-weather, etc.

The large number of coupe types indicates the growing demand for these all-year cars. The majority are constructed somewhat on brougham lines, and the two and three-passenger designs predominate, although instances of larger capacities are noted. With some two-passenger styles provision is made for a third person by using a drop seat. Curved roofs with graceful lines are much favored, and the front glass is usually a divided windshield of the clear vision type. The side and rear panes are generally two each, although instances of three side members are noted. As a general rule, the glasses are very large, following the tendency toward narrow framing and large glass panels. The upholstery is in Bedford cord and grain leather. In several instances, with three-passenger designs, the driver's seat is slightly ahead of the passengers, a commendable arrangement. Provision is also made for the storage of luggage.

That there is a constantly increasing demand for a town car is evidenced by the large number of

makers producing high grade berline and sedan types of limousines. The pronounced roof curve of a year ago is disappearing in favor of the softly rounded style, and there are more examples of doors arched into the roof than formerly. The use of larger windows, and of the sashless type, is gaining many adherents.

The sedan is generally a single compartment vehicle, admirably suited to the owner who drives. It is distinguished from the coupe by the forward seat of the driver and the rear seat

for the passengers. As with the coupe, the sedan type is intended to be operated from the same compartment as that in which the passengers sit, either by the chauffeur or the owner, and in this respect is in contrast with the limousine. The sedan has a curved top as a rule, and but one door to each side. One maker employs a single door, placing it on the right.

Beautiful examples of the coach builder's art are noted in the limousine, over 40 per cent. of the car manufacturers having either altered the style or marketed new designs. The general tendency is toward enclosing the driver's compartment and utilizing a slight rise in the body frame over the door. The general lines of the roof are the same as those used on the sedan. The upholstery and interior fittings are in keeping with the rich designs, many bodies being upholstered in soft textures of dainty hues.

Several ingenious

Richly Upholstered Interiors and Folding, Disappearing Seats Are Features of 1914 Body Designs.

Unconventional Spring Suspensions: A, Form of Cantilever on National; B, Rear Spring of Hupmobile; C, King Cantilever; D, Lanchester Cantilever Rear Springs on Willys-Knight.

examples of intermediate or extra seats are noted, both in the enclosed and open types of cars. Some are of the disappearing type, folding into a recess in the back of the front seats or into the floor, while others may be compactly folded and into a small compass. The majority of the seats in the enclosed bodies follow standard lines in swinging back out of the way when not needed and in having backs that fold.

Roomier Bodies.

Six and seven-passenger touring bodies are roomier than ever and there is a wide choice to be found. It is noticeable that more room is provided between the rise of the front seat panels and the forward edges of the rear seats, even when intermediate seats are not fitted. The width of the rear seat in some models is such that, coupled with its being placed well to the rear of the rear axle, on certain roads the passengers will seek intermediate seats when a full complement of passengers is not being carried.

The five-passenger touring body is the popular type, and seems more in demand than the four-passenger. The lines rarely differ from those of the large models made by the same companies, and with few exceptions additional tonneau seats are not provided. Some idea of the wide choice offered the buyer may be obtained from the statement that there are over 200 different five-passenger touring cars and that there are approximately 30 different models listing at under \$1250. In those cars listing between \$1250 and \$1999 there are about 64 styles.

It is noticeable that the 1914 touring bodies embody refinements that previous models lacked. The most important departure from standard design is the transition between the hood and the body, the abrupt break at the dash having been eliminated by the cowl, which is a continuation of the hood and extending back makes possible the streamline effect so popular abroad. To accentuate this effect many makers have discarded the side lamps, utilizing double-bulb headlights, the smaller bulb serving for city and

town use. One-man tops, so-called because they may be raised and lowered quickly by one person, are standard equipment with several makers.

The problem of storing the side curtains when not in service has been solved by patented storm curtains, such as the Jiffy and the Collins, and those designs operated without getting out of the car. In several instances these curtains are made to match the upholstery of the machine.

What is without doubt the most practical accessory added to the already complete equipment is the power tire pump. Several makers anticipated the demand, while others have made provision for its installation. The adoption of the power tire pump has eliminated manual inflation, a problem that was not wholly solved by the convenience of the demountable rim.

Power Tire Pump Popular.

Several methods of locating and driving the power pump are shown in accompanying illustrations. In many instances drive is taken from

Illustrating Standard Practice in Mounting and Driving the Power Tire Pump and Use of Universal Joint for Speedometer Drive.

a gear mounted on the shaft actuating the water pump, magneto, etc., the gear on the pump being thrown into mesh with the driving member by a lever, or a form of clutch arrangement employed to connect the driving and driven members. One maker takes the drive from the same shaft on which the fan pulley is mounted. The efficiency of these power pumps is such that the largest tire may be inflated in from one to three minutes, depending upon the capacity of the pump.

Motor Starters Vary.

The past year has resulted in something like an approach to standardization in the mounting of the lighting generator and motor starter. Last year the methods were extremely varied, which may be said to have been due, in the majority of cases, to the necessity for adopting the system that could be obtained in time for the annual

ature shaft to the toothed periphery of flywheel.

The general tendency is to incorporate in the end cover of the motor a first reduction gear of 2:1 or 3:1, including an overrunning clutch in one of these gears, and obtaining a further reduction of approximately 8:1 or 10:1 between the sliding pinion and the flywheel. Meshing is made easy by connecting the shifter mechanism with the starting switch. The flywheel method of installation makes possible the location of the motor in front of or behind the flywheel and above or below the centre.

Single-Unit Types.

The next largest class employs a silent chain drive, but its application varies considerably, according to the system. With the single-unit type—the motor-generator—the gear ratio or drive changes considerably when the unit is being utilized for starting and for generating current. This

Illustrating Varying Installation of Lighting Dynamo and Motor Starter, Also Method of Applying Energy of the Latter: A, Krit Utilizes Tandem or Double Decker; B, Chalmers; C, Chandler; D, Jackson, a Vertical Installation with Drive Through Worm and Chain; E, Compact Grouping of National Units; F and G, Buick; H, Marmon; I, Motor Starter on Mitchell; J, Franklin.

displays, and, in many instances, applying it as best accommodated to the particular design of motor.

Flywheel Type the Vogue.

The method of installing the motor starter depends largely on the spaces available about the motor, which vary considerably in the different makes of engines. Where the manufacturer has brought out a new power plant provision has been made for imparting the energy of the electric motor, but in the majority of instances the unit has been applied without altering the design of the engine other than by adding a ringed gear to the periphery of the flywheel. This form is utilized by approximately 50 per cent. of the makers, it comprising the application of the power of the starter through a pinion on the arm-

is accomplished by the use of a reducing gear, which comes into action when the system is employed for starting. It is usually of the planetary type or some modification of it. The third class imparts the energy of the motor through the pump or magneto shaft to the timing gears, thence to the crankshaft. This method is practically a variation of the second, in that the timing gears are utilized to obtain the amount of necessary reduction.

Use Reduction Gearing.

Another method is that of mounting the motor beside the gearbox and driving into a gear on the main shaft in front of the gearbox. Meshing of the gears is effected by a pedal working a sliding gear, at the same time making the necessary electrical connections. The starting motor in

Mechanical Details of 1914 Models: A, Moline-Knight Oil Filler; B, Controls on Paige; C, Marmon Utilizes Universal Joint of Steel Rings; D, Pilot Uses a Friction Driven Tire Pump; E, De Soto's Pedal Operated Emergency Brake and Automatic Latch.

this instance is geared to the crankshaft at 25:1, gear ratio, and as soon as the engine operates under its own power a three-wheel clutch allows it to overrun the starting motor, to prevent injury to the gears or the armature. This overrunning clutch is necessary with almost all starting equipments, to protect the motor. In cases where the drive is by silent chain to the crankshaft, the clutch is usually incorporated in the chain wheel. In the flywheel method it is fitted in the second gear of the reduction.

Operation of Clutch Device.

The tandem or double-deck arrangement of the motor and generator is favored by many makers because of its compactness. The drive from the starting motor is usually taken through the armature of the dynamo half of the unit. If the car be standing, and the motor switch thrown in, the motor armature actuates a train of reduction gears between the two armatures. One of these gears is not permanently attached to the generator shaft, but operates through an overrunning clutch, a device that permits of drive in only one direction and which consists of an inner steel member containing recesses in which are hardened steel rollers. When these rollers occupy the larger end of the recesses the motion of the clutch is not affected, but upon one of the driving gears attempting to turn in the opposite direction, the rollers move along the recesses, locking and making the whole practically a solid drive. Power is transmitted to a pinion on the opposite end of the generator armature shaft, thence to the crankshaft by chain. Upon the engine starting to operate under its own power, there is a tendency to spin the motor at high speeds, represented by the reduction

gearing, but the roller clutch comes out of action and prevents this. The generator armature then begins to rotate, the unit functioning as a dynamo.

Varying methods of mounting the motor starter are shown in an accompanying illustration, with the exception of the flywheel type, which has been fully explained. It will be noted that one maker mounts the motor starter vertically at the front

end of the engine, and utilizes a worm gear on the armature shaft, which engages a large gear on the countershaft. Keyed to the large gear is a small sprocket, from which a chain runs to the free member of ratchet starting clutch. This member is free to revolve on shaft, while the other member moves in and out of engagement on splined shaft with which it rotates. When the clutch is not engaged, the motor is entirely free from the starting mechanism, and can rock back and forth without restriction. A foot switch controls both the clutch and the starting motor.

Locating Two-Unit Types.

Where the two-unit system is employed, which is favorable to the six-cylinder power plant, the lighting generator is driven by the same shaft, or its extension, as that which drives the water pump and magneto. Several instances are noted where the dynamo is located at the forward end of the power plant and actuated by an auxiliary shaft, while the motor starter is mounted at the rear on the same side. Several makers have discontinued the magneto, utilizing the current generated by the dynamo for ignition and employing a distributor.

Torque Rods and Yokes: A, Buick Torque Yoke; B, Chalmers Torque Rod Connection; C, Forward End of Oakland's Torsion Rod Is Supported Above Drop Frame; D, Leather Universal Joint Used on Jeffery; E, Flexible Universal Joint on Willys-Knight; F, Flexible Magneto Coupling Employed on Stearns-Knight.

Constructional Details: A, Novel Breather on Stutz; B, Fan Belt Adjustment on Auburn; C, How Body Noises Are Eliminated on Chalmers; D, Compact Grouping of Controls on Keeton; E, Eccentric Adjustment of Marion's Fan Pulley.

Further evidences of electrifying the gasoline vehicle are noted in the electric gearshift in which the desired changes of speed are obtained by pressing a button on the steering wheel and utilizing the clutch pedal in the conventional manner. The shifting of the gears is accomplished by solenoids or magnets. Indicative as to what may be expected in 1915 is the announcement of the Entz electric transmission, which comprises a generator, motor and battery, these replacing the flywheel, clutch and gearset, and providing eight speeds controlled by a small lever mounted on the steering wheel. The lever also controls the starting, and changes in speed are accomplished by increasing or decreasing the slip between the field and the armature of the generator. The so-called "slippage" results in the generation of electric current, which is fed to the electric motor utilized to augment the power applied to the rear wheels when the low and intermediate speeds are employed. Upon the car attaining certain speeds, the electric motor is cut out, and it functions as a generator. Announcement also has been made of an electric brake which was exhibited at the New York show.

Mechanical refinements have been toward obtaining increased efficiency and silence. As a result of a finer balancing of the reciprocating parts, vibration is reduced to a minimum. In the endeavor to obtain silence many details have been improved. It is now becoming general practise to utilize flexible connections, as between the driving shaft and armature shaft of the magneto for ex-

ample, and some makers have adopted flexible universal joints. One manufacturer has made use of this arrangement between the clutch and transmission. It was first introduced abroad by Daimler to eliminate friction in the transmission of power. Sudden application of energy to the driving mechanism is held to be eliminated.

While it would appear that the leather utilized would not withstand the stresses to which the universal joint is subjected, it is stated that tests have shown that natural tanned leather will

withstand a twisting strain of 17,000 pounds, which is approximately 15,000 pounds above the normal strain existing in practise. One maker employs a single leather universal and places in front of it a slip joint. Another manufacturer utilizes steel rings as a material. Adjustable magneto couplings are now used by several makers and these are of decided value, in that the spark timing may be altered through a range of two degrees without having to reset the gears.

Improved Carburetion.

The cost of gasoline, and the demand for maximum mileage a gallon, have resulted in the use of larger valves, improved intake and exhaust manifolds and means for raising the temperature of the fuel. The carburetor is placed higher and in proximity to the water jackets, a position making for easy access, and one appreciated by the owner who cares for his car.

Many manufacturers realize that the number of motorists driving and maintaining their ma-

Spring Constructions and Suspensions: A, Moline Method of Extending Frame to Protect Fuel Tank and Attaching Rear End of Semi-Elliptic Underslung Rear Springs; B, Spring Eye on Franklin's Front Springs; C, Rebound Spring Device on Empire; D, Intake and Exhaust of Packard; E, Speedometer on Apperson Is Driven from Universal Joint.

chines is rapidly increasing and many components that formerly were not easily accessible may now be inspected with a minimum of labor. Simplicity and accessibility are features of the 1914 chassis.

A review of the chassis reveals the fact that designers are giving more attention to the mounting of the brake and pedal shafts and control levers. While it is a simple matter to attach a cross shaft to the side frame rails through the use of bearing brackets on either side, and to mount the clutch and brake pedal on it, yet trouble is experienced. Every car frame is subjected to a certain amount of variation in the relative positions of the side frame members, due to road inequalities, and allowance must be made for this frame movement. Unless the cross members are rigidly mounted and braced, slight changes in their position tend to cause binding of the shaft-carrying the clutch and brake pedals.

The majority of engineers realize this point and where cross shafts are utilized to carry pedals, a cross member parallels this shaft, in

proximity to it, so that movement is practically eliminated. Examples of efficient design are most noticeable in the unit power plant, which lends itself readily to correct mounting of the brake and clutch operating mechanism. The shaft carrying the pedals is easily bracketed to the side of the gearcase, and, being free from the frame, entirely eliminates opportunity of binding through movement of the last named.

Lubrication has been improved and simplified. Instead of a multiplicity of exterior piping and connections, the system in the majority of instances is self-contained in the motor. As a result the dash sight feed is disappearing. Attention has also been paid to maintaining the lubricant at predetermined temperatures, breathers have been improved, and the devices indicating the supply of oil are conveniently placed.

Summarized, the prospective purchaser of a 1914 model is offered a larger variety of cars to choose from; receives decidedly more value for his money than formerly, and is assured of maximum service at minimum upkeep expense.

TAKES OVER AXLE PATENTS.

Kardo Company, with \$1,000,000 Capital to Issue Licenses to Car Manufacturers.

An announcement of unusual interest to the industry is made in connection with the organization of the Kardo Company, Cleveland, O., Feb. 26. It is understood that the concern, which is capitalized for \$1,000,000, will be in the nature of a holding company, taking over certain axle patents heretofore held by the Packard Motor Car Company, Detroit; Peerless Motor Car Company, Cleveland, and American Ball Bearing Company, Cleveland. The officers are: President, Alvan Macauley of the Packard company; vice president, Theodore W. French, Peerless; secretary and treasurer, Fred C. Dorn, American Ball Bearing Company. The directors include: F. S. Terry, connected with the National Electric Lamp Company, a General Electric subsidiary; Walter C. Baker of the ball bearing company, and Milton Tibbetts, patent counsel for the Packard company. The published statement of the company follows:

The Packard Motor Car Company, the Peerless Motor Car Company and the American Ball Bearing Company, have, since the earliest days of the industry, independently and at large expense, developed axles that they believe are best suited to their respective trades. The patents on these axles, pertaining as they do to component parts, are so closely correlated and interlaced that the axles of either of the companies cannot be built without infringing the patents of the other companies.

This three-cornered patent situation has been a vexatious question for some time, each company claiming that the others and the trade generally infringe its axle

patents, and litigation has been frequently threatened. The situation became so acute and disturbing recently that a way was sought to relieve it. Careful study made it evident that the industry, including the three companies whose patents were directly involved, and automobile users generally, were interested in the final outcome and would be benefited by the removal of the menace and the avoidance of expensive and wasteful litigation. It seemed, therefore, that the patents should be so owned that licenses under them might be enjoyed upon reasonable and equitable terms by all manufacturers and users.

The patents are now owned by the Kardo Company. Some licenses under them have been granted and the company is negotiating others at the present time. Of course the usual royalty reservations will be made, and manufacturers will receive licenses that will insure them the right to make and sell to their customers axles that are free from charges of infringement. It is sincerely hoped and confidently expected that no litigation whatever will be necessary to the accomplishment of this constructive work.

GASOLINE STILL CHEAPER.

Another Reduction of One Cent Due to Severe Winter and Increased Production.

As announced in the last issue of The Automobile Journal, the price of gasoline was reduced Feb. 24, from 17 to 16 cents a gallon in 50-gallon lots or more. During the second week in March, a second reduction was announced by the Standard Oil Company, Texas Company and Gulf Refining Company, bringing the wholesale price to 15 cents. The reasons assigned for these reductions are: The severity of the winter, and the increase in production, particularly in Oklahoma and surrounding territory, where several new refineries are said to have been opened.

MORE WORKING CAPITAL.**Stockholders of Goodyear Tire & Rubber Company Approve Financial Plan.**

Without a single dissenting vote the stockholders of the Goodyear Tire & Rubber Company, Akron, O., at a special meeting, March 3, approved the plan of the directors for introducing \$4,000,000 of new working capital by the sale of stock. It is understood that already present Goodyear stockholders have subscribed for more than 80 per cent. of the stock to be offered, and it is anticipated that the rest of the offering will be taken by them before the rights expire.

It is explained by officials of the company that additional working capital was made necessary by the growth of business. Since 1911 this has increased from \$13,000,000 a year to \$33,000,000, on the basis of \$10,000,000 capital stock. In the meantime, the company has just completed additions to its factory sufficient for the handling of an annual business of \$50,000,000.

It is added that it is expected that the pneumatic tire output will shortly reach 10,000 a day. Comparative figures for three months of the present fiscal year with those for the same three months a year ago, show an increase in tires sold of 47, 55 and 82 per cent. respectively.

THE AJAX FROM SEATTLE.**Company Organized on Pacific Coast to Produce an Entirely New Six-Cylinder Machine.**

The Ajax Motors Company, headed by Seattle men and incorporated under the laws of Arizona, has been organized in Seattle, Wash., for the purpose of producing the Ajax car, a six-cylinder machine, which will be presented in two chassis, one fitted with a poppet valve motor and the other with an engine of the piston valve design. The list of incorporators includes George, Frank L. and Charles L. Parker.

Both engines will be six-cylinder units, with bore of 4.5 inches and stroke of 5.5, cast in pairs. The transmission will afford four forward speeds and reverse. No radius rods will be employed, the drive being taken through the two rear springs, transmission case, propeller rod housing and a ball and socket joint in the centre of the car.

Three styles of bodies will be offered as standard, these being roadster, phaeton and touring, the latter being designed for five and seven passengers. Limousine bodies also may be had

upon order. The wheelbase of the roadster will be 120 inches, of the phaeton and five-passenger touring 133, and of the seven-passenger and limousine 136. The Ward Leonard system of lighting and starting will be employed. It is expected that the company will be in a position to make deliveries from a plant in Seattle about Oct. 1.

ANOTHER BRISCOE COMPANY.**Will Produce Argo Machines in Factory Located Just Outside of New York.**

The Argo Motor Company has been organized in New York City for the production of a light car in a factory to be located just outside of the city, according to the preliminary announcement. The officials of the company are:

President and general manager, Benjamin Briscoe; vice president and general sales manager, L. E. Latta; secretary and treasurer, F. D. Dorman. Associated with these officers are a number of engineers, factory men and dealers who have had a part in Mr. Briscoe's former enterprises.

**F. D. Dorman, Secretary-Treasurer,
Argo Motor Company.**

Although it is maintained by the company that the product will not be a cyclecar, but a light automobile, the advance description would seem to indicate that the motor dimensions and weight were to be such as to place it in the true cyclecar class. The engine will be a four-cylinder unit, with bore of 2.31 inches and stroke of four, giving a piston displacement of 67 cubic inches. The weight is to be about 700 pounds. The wheelbase will be 90 inches, and the body will seat two passengers side by side. Thermo-syphon cooling, splash lubrication with pump circulation, cone clutch, sliding gear transmission, shaft drive, full elliptic springs and wire wheels 28 inches in diameter are among the constructional details revealed.

RECEIVER IS APPOINTED.

Announcement Also Is Made of Proposed Organization of New Company.

Upon application made by the directors of the Palmer & Singer Manufacturing Company, Long Island City, N. Y., maker of the Palmer-Singer car, John J. Kuhn, a lawyer, of the firm of Dykman, Oeland & Kuhn, New York City, has been appointed receiver by Judge Veeder of United States court in Brooklyn, N. Y. This action has caused some little speculation in financial circles, since it took place practically coincidentally with an announcement that Charles A. Singer, president of the concern, was preparing plans for the formation of a company to produce a new car, to be known as the Singer.

S. P. Woodard, secretary of the Palmer & Singer Manufacturing Company, is quoted in a published statement as follows:

It is stated by the officers of the company that the cause of this action was the fact that developments along certain lines during the last nine months had not proved profitable. Costly experiments were introduced, which at the present time have not been perfected and cannot be continued because of want of working capital.

The officers further stated that the cause of the present situation was not any inability to market Palmer-Singer cars, but that the demand for these cars continues in an increasing volume. On account of the first mentioned developments, the officers of the company felt it advisable to conserve the interests of the creditors and stockholders of the company by a receivership.

From other sources, it is understood that there has been some little difference of opinion between stockholders with reference to the experiments mentioned in the above statement. Some months ago the Palmer & Singer Manufacturing Company announced its intention of fitting 1914 models with a new type of motor, and Mr. Singer has been actively engaged in perfecting the details in connection therewith. Whether or not the new Singer car is to be equipped with this engine has not been made public. Mr. Singer is quoted as saying that the orders for Palmer-Singer cars on the books of that company at the first of the year were in excess of past records and more than sufficient to maintain the running capacity of the plant.

TO MAKE WOODWARD PUMPS.

Concern Is Organized in Detroit for This Purpose with Capital of \$50,000.

The Woodward Pump Company has been incorporated in Detroit, for the manufacture and distribution of the Woodward Impulse tire pump. The concern has capital of \$50,000, and the head-

quarters of the company are located at 222 Third street. The officers are: President, A. Woodward; vice president, E. L. Ackerman; treasurer, C. E. Blaesser; secretary, C. B. Woodward.

The Woodward pump was placed in the market in 1913, and is said to have met with decided success. It also is stated that the firm of Joseph N. Smith & Co., of Detroit, of which E. L. Ackerman is president, is largely interested in the new concern, and that the pump will be produced in its factory.

NEW STUTZ FACTORY.

Plans Completed for Erection of Structure Required by Increasing Business.

The Stutz Motor Car Company, Indianapolis, Ind., with which has been incorporated the Stutz Auto Parts Company of that city, has completed plans for the erection of a new factory building at Tenth street and Capitol avenue boulevard. It is understood that the erection of this structure was made imperative by the increasing demand for Stutz cars.

The building will be four stories high, of fire-proof construction throughout, and will cost about \$100,000. Work will begin about April 1. When completed the general offices of the company, which are now located at 430 North Capitol avenue, will be removed thereto.

PURCHASES NYBERG PLANT.

A. C. Barley Expected to Consolidate This with Streator Motor Car Company.

It was announced in the last issue that A. C. Barley of Chicago had purchased the Streator Motor Car Company's plant in Streator, Ill., and that it was expected that this concern would soon resume the manufacture of Halladay cars. Additional information from Streator states that Mr. Barley also has purchased the plant of the Nyberg Automobile Works, Anderson, Ind., the price paid being \$7500 in cash and the assumption of liens amounting to \$22,000.

It is now understood that it is the intention of the new owner to consolidate the two plants and to produce both the Halladay and the Nyberg for the 1915 season. It is further stated that two very low priced models, perhaps a cyclecar, will be added to the line.

George Uihlein of Milwaukee has become general manager of the Universal Motor Truck Company, Detroit, succeeding F. K. Parke.

NEW ACCESSORIES FOR THE MOTORIST.

SMITH EASY TIRE VALVE.

Replaces Usual Construction and Reduces Labor to a Minimum.

The Smith Tire Valve Company, box 1965, Boston, is marketing the Smith easy pumping tire valve,

which comes in sets of four and is moderately priced. It is easily attached to the valve stem, the plunger of which is removed, as the Smith replaces this member. One of the qualities of the Smith device is that the largest sized tire may be inflated with a minimum of effort with a hand pump. Another feature that will appeal to owners is that the Smith valve opens with a very slight pressure, permitting of utilizing the pump from the beginning to the end of the stroke. This makes for economy of time, in that it is figured that approximately 60 per cent. of the stroke is required to open the ordinary tire valve.

STEWART CARBURETOR.

Special Ford Design, Dash Adjusted and Heated by Hot Air.

The Detroit Lubricator Company, Detroit, manufacturing the Stewart carburetors, has developed a design for the model T Ford motor, which is held to be very efficient, easily installed, and to make use of the heat of the exhaust manifold. It is supplied either with thumb screw adjustment or to utilize the regular Ford dash adjusting rod.

The principle of operation of the Stewart is held to be entirely different from conventional types, and the maker states that the proportions of fuel and air are accurately determined, irrespective of the throttle

opening. Use is made of a metering valve, which moves up and down, according to the suction of the motor, and it is held that the amount of fuel and air admitted to the mixing chamber increases or decreases in exactly the same ratio, obtaining the correct proportions at different speeds.

The lower end of the metering valve extends down into the gasoline and around a taper. Because of the decreasing diameter of this pin the higher the metering valve is lifted the larger will be the opening into the aspirating tube, and the more fuel will be drawn up. There is but one moving part, the metering valve.

NODAZ.

Electrically Controlled Device for Eliminating Glare.

The Ward Leonard Electric Company, Bronxville, N. Y., maker of electric lighting and motor starting systems, is producing Nodaz, which is held to be a solution of the dazzle problem. In other words, the device permits the use of the electric head-

lights at full candlepower in the cities without conflicting with ordinances.

It comprises two pairs of translucent wings pivotally mounted in the reflector. These wings are opened and closed by magnets within the cover of the lamp, and are operated by pressing a button. With the wings closed, there is no glare, but it is stated there is a strong, diffused light, sufficient for operating on country roads. Pushing another button opens the wings, obtaining the usual rays.

It is stated that whether the wings are folded or open, they do not perceptibly affect the efficiency of the bulbs, as they are very thin. The magnets controlling the device require but little current for operation; less than half that necessary with a horn, it is stated. One of the qualities of the Nodaz is that it may be attached to any headlight. In the illustration, the wings are shown folded or open. It is moderately priced.

Always consult the Classified Buyers' Guide when accessories, supplies, fittings, etc., are desired. The concerns listed are wholly reliable and worthy of your consideration in every way. The Guide is alphabetically arranged.

RUSCO FORD FAN BELT.

It Is Woven Endless and Is Uniform Throughout.

Few motorists give the fan that consideration it deserves. The majority are content if it operates at

sufficient speed to keep the motor cool, and as a rule it is only when the cylinders show signs of heating that the tension of the belt is adjusted. With high speed motors, such as the model T Ford for example, it is essential that a high grade, properly adjusted fan belt be used.

The Russell Manufacturing Company, Middletown, Conn., is producing a fan belt for the Ford car that is woven endless, and the maker states that it will not stretch and is not affected by heat, moisture, etc. It is guaranteed to be uniform throughout and to give perfect service. It is not only inexpensive, but comes packed in a neat box.

NATIONAL REFLECTOR.

A High Grade Design for Acetylene Headlights.

The National Reflector Company, Clarksburg, W. Va., is manufacturing the National reflector, a design for acetylene headlights, and the maker lays great emphasis on its durability and efficiency. It is made of blown glass, and it is stated that the double-wall construction gives both great strength and lightness. The silvering is inside of the reflector, a construction held to prevent cracking and peeling. That sudden changes of temperature will not injure the reflector, and that it will not become discolored in service, are claims made for the design.

CENTURY CIGAR LIGHTER.

Operates on Any Six-Volt Battery and Is Nicely Finished.

The Century automobile cigar lighter is marketed by Mabey's Electric & Manufacturing Company, Indianapolis, Ind., and is a very neat, compact design. It is made to operate on a six-volt storage battery or dry cells, and comes finished in black leather with all trimmings nickel plated. The switch is well designed, is of the push type, and included with the equipment is seven feet of silk cord. The dimensions of the Century are one by two inches. In attaching to the car the maker recommends running the cord from the battery up through the floor at the back of the front seat so that the lighter will be convenient for all passengers.

The company is also marketing an electric radiator heater for preventing freezing of the water in the cooler. The wiring plan is such that the usual storage battery and garage lighting system are utilized independently.

STANDARD TIRE PROTECTOR.

Reinforces Side Walls as Well as Tread of Shoe.

Announcement is made by the Goodyear Tire & Rubber Company, Akron, O., that it has formally taken over the manufacture and sale of Standard tire protectors as a part of its automobile tire department. This action follows several years of watching, testing and investigation, and the company believes that there is a legitimate and useful field for the device.

The Standard tire protector is simply a tire tread, fashioned separately. It not only comes well down over the side walls of the casing to which it is applied, protecting them, but is so ingeniously constructed that when once applied it remains firmly in place without any other fastening than the inflation pressure of the tire to which it is applied and covers.

It is stated that it is quickly and easily applied, and that it cannot injure a tire carcass, as vulcanized repairing frequently does. It is also held to be available for service if the old casing gives out sooner than expected. The Standard is intended to obtain more mileage from shoes that are worn on the tread, but still strong as to side walls. It effects tire economy, especially in the larger tire sizes.

TRIO FILTER.

Made for Standard Models, Also Special Design for Ford Car.

The Trio Manufacturing Company, 1206 Bellevue avenue, Detroit, is marketing a combination sediment trap and gasoline reserve supply device which is intended to eliminate the necessity for carrying extra fuel. It is designed especially for those cars not equipped with auxiliary fuel tanks, and the maker states that the Trio not only insures a reserve supply of fuel, but makes a rigid tank connection.

It has a sediment trap to catch all foreign elements, and is also provided with a positive shut-off to the carburetor. A petcock at the bottom of the Trio permits of drawing fuel for priming purposes, etc.

The illustration shows the valve in

a closed position. When the lever is turned to a forward position, the reserve supply is obtainable. With the lever turned half-way over to an opposite position, the tank may be drained. The valve is of large dimension and is ground to a gasoline tight fit, and comes ready to install. It is stated that it may be fitted in 15 minutes and that the services of an expert are not required. The company is marketing a special design for Ford cars.

NEW EQUIPMENT.

With the approach of spring the thoughts of the motorist turn to the overhaul and new equipment. The manufacture of a large number of devices eliminating much of the hard labor that formerly existed, has resulted in many owners undertaking the work of placing the machine in order. In this department will be described new and special tools, as well as equipment that makes operation and maintenance easy.

C-S FORD REFLECTORS.

High Grade Design with Many Practical, Useful Features.

The Culver-Stearns Manufacturing Company, Worcester, Mass., is marketing the C-S patented lighting out-

fit for model T Fords, which is designed to operate direct from the fly-wheel generator. The outfit consists of one pair of heavily silver plated reflectors, all necessary wiring, bulbs, switch, Ediswan connectors, etc.

One of the qualities of the design and one which will appeal to owners of Ford cars contemplating converting their gas lights into electric units, is that in the event a bulb becomes burned out or broken, it may be removed and a new one fitted without displacing the reflector. This is made possible by a patented device at the rear of the reflector, it being displaced by loosening a knurled nut and rotating the part slightly.

THE VOTEX.

Automatically Admits Air to Intake Manifold, Weakening Mixture.

The Sireno Company, 20 Rose street, New York City, is marketing the Votex, which is fitted in the intake manifold between the carburetor and the cylinders. It is held to be automatic in its action, delivering a certain amount of air to an imperfect mixture, and as required. The action of the Votex is stated to be as follows:

When the motor is operating idle, the Votex allows a small amount of air to enter the intake manifold, partially relieving the suction of the engine and weakening the mixture. When the throttle is opened quite wide the vacuum in the manifold is relieved and allows the Votex to close, enriching the mixture. When the motor gets up to speed the throttle is closed down and a very high vacuum is again created in the manifold, thus allowing the Votex to open and supply air, weakening the mixture to an economical point.

PERFECT VALVE LIFTER.

Compresses Two Springs at Once and Is Designed for Ford Cars.

Winton L. Smith, 78 Clinton street, Newark, N. J., is marketing the Perfect valve grinding set, which is de-

signed especially for the model T Ford motor. The equipment comprises the Perfect valve spring lifter, valve turning tool, wrench socket, grinding paste, gauge and complete instructions. The application and use of the valve spring lifter is shown in the accompanying illustration. It comprises a plate which fits under the spring washers and the lifter, which is fitted over the pushrod housing.

By rotating a nut on a threaded bolt integral with the lifter, two springs are compressed, enabling easy removal of the lock key. The wrench socket is utilized for displacing the cylinder bolts. The paste comes in two tubes, fine and coarse abrasive. The gauge referred to is utilized to determine the correct distance between the pushrods and the tappets. The equipment comes neatly packed and is moderately priced.

SHALER VULCANIZER.

Safety Vul-Kit Is Adaptable to Tires and Inner Tubes.

The C. A. Shaler Company, 850 Fourth street, Waupun, Wis., maker of vulcanizing equipment, has brought out the Shaler Vul-Kit vulcanizer, which is offered at a very attractive price. It is the result of considerable experimentation to develop a vulcanizer that could be carried easily in the tool box and be operated anywhere at any time, thus making it adaptable for roadside repairs.

The maker states that there is no danger of fire if the device be accidentally upset, and that the fuel supply is limited to that required for perfect vulcanization. To operate it is filled with fuel and lighted.

When a tube is to be vulcanized it is clamped against the vulcanizing surface by a swivelled plate inlaid with asbestos to retain the heat and to prevent pinching the tube. It is stated that a repair cannot be spoiled by clamping one side of the plate more tightly than the other. The handle is always cool, permitting of removing the vulcanizer from the work as soon as the repair is finished. The Vul-Kit is adaptable to casings and without removing the latter from the rim.

MOSCO FORD WHEEL PULLER.

Fits All Ford Cars and Is Adjustable to Hub Threads.

The Motor Specialties Company, Waltham, Mass., with New York office at 50 Church street, is producing the Mosco anti-rattling ball sockets, which are constructed in two sizes for the model T Ford automobile. The larger model is utilized to eliminate lost motion and rattling of the front radius rod, it replacing the cap member. The smaller size is used in place of the ball socket cap on the steering gear connecting rod. Both the parts referred to are subject to wear, as provision is not made for

lubricating them, consequently in time lost motion develops in the steering linkage.

The Mosco conforms to the dimensions of the Ford parts, and is easily attached, the usual bolts being utilized. It is provided with a plunger, the end of which conforms to the shape of the ball end of the parts, and a cushion device is incorporated to absorb road shocks and prevent these being communicated to the hands of the driver. Means are provided for taking up any lost motion in the Mosco. It is made of high grade material and is moderately priced.

CARBON REMOVERS.

The editor of this department has received several letters from readers relative to the merits of the fluid and dry carbon removers marketed. Personally he has had no experience with them. The fact that they have been on the market some time is indicative of their merits. In the opinion of the writer the oxygen process is decidedly satisfactory. The equipment is not expensive and there is no reason why several owners living in the same neighborhood could not club together and purchase an outfit.

A. A. A. FORD HUB CAPS.

Substantially Constructed, Plain and with Initial Letters.

The A. Auto Appliance Company, 114 West Exchange street, Providence, R. I., maker of Ford special-

ties, is manufacturing several models of Ford hub caps, which are not only attractive, but are substantially constructed. They are cast in bronze, then machined to size, and the threads are accurately cut. The caps are of sufficient thickness to withstand severe service and one of the qualities emphasized by the maker is that they cannot be crushed when force is utilized to remove them if they become frozen.

The edges are scalloped and the usual hex head is provided for removing and replacing with a wrench. Each cap is nickel plated and highly polished. The A. A. A. Ford caps come plain and with initials, and their use considerably improves the appearance of the machine.

NEW KLAXON HORN.

Designed for Motorcycles and Is Manually Operated.

The Lovell-McConnell Manufacturing Company, Newark, N. J., maker of the Klaxon line of horns, has brought out a model for motorcycles which is exactly like the regular hand Klaxon for automobiles except that it is fitted with a short projector and a special clamp for attaching to the busbar of the motorcycle.

It provides the motorcyclist with an efficient signal, one that is operated without the service of batteries. It operates on the Klaxon principle of a vanadium steel diaphragm vibrated by a high speed cam wheel. In the case of the electric Klaxons this wheel is rotated by an electric motor; in the motorcycle design by a train of gears that attain high speed under the pressure of the pushrod. The new model has the true Klaxon note and is sold under usual Klaxon guarantee, covering service, etc.

WITH THE CYCLECAR MANUFACTURERS.

New Models Being Announced Very Rapidly, and Work of Testing Machines Is Progressing in Satisfactory Manner--Falcon and Imp Have Experience in Snow.

NEW ENGLAND has been experiencing, during the present week, its first opportunity to view the latest arrival in the automobile industry, and, as was expected, this was made the occasion for presenting new cyclecar models. The term is used in its general sense, since the machines on exhibition at the Boston show might be held to include representatives of all three classes under the definitions of the Cyclecar Manufacturers National Association.

The designs revealed at the Boston show, or in connection therewith, are presented in detail elsewhere in this issue. It has been deemed best to reserve the space available in this department to a more general consideration of the cyclecar end of the industry, and it will be noted that the number of new makes that have been announced in the past two weeks is sufficient to

tion of the engineers, and some of them cannot well be determined until the cyclecar has seen actual daily service in the hands of owners. Such long distance tests as machines have been subjected to appear to indicate their thorough practicability. The summer of 1914 will do much toward eliminating any doubts that still remain. The cyclecar—true cyclecar, light car and small car—is here. The public is invited to help make it an established institution.

DETAILS OF KELLER-KAR.

Maker Has Decided to Replace Two-Cylinder Motor with a Four-Cylinder Engine.

Although the original model produced by the Keller Cyclecar Corporation, 143 North Dearborn street, Chicago, was equipped with a two-cylinder, air-cooled motor of 3.5-inch bore and 3.625-inch stroke, it has now been decided to utilize a four-cylinder, water-cooled engine with bore of 2.5 inches and stroke of three. This does not change its classification, under the rules of the Cyclecar Manufacturers National Association, of which the concern is a member. The officers of the company are the following: President and treasurer, Paul A. Keller, and vice president and secretary, H. P. Keller.

The motor dimensions and the weight, 425 pounds, place the machine in the true cyclecar class. Lubrication is by splash, carburetion by a Schebler and ignition by Atwater Kent Unisparker. Power is transmitted by friction discs, and final drive is by Peerless V belts. Springs are inverted elliptic, which might be termed another name for cantilever.

The frame is of steel, cellular construction, and the body, also of metal, provides for seating two passengers tandem. The seats are upholstered in leather, and the car is fitted with an electric lighting system. The wire wheels carry 28 by 2.5-inch tires. The wheelbase is 96 inches and the tread 36.

The Keller-Kar Is a True Cyclecar with Four-Cylinder Motor and Tandem Seating Arrangement.

make a very respectable showing of themselves.

With the approach of spring, there is every indication that those who are desirous of securing a cyclecar will be confronted with a long list from which to make selection. In many instances it will be found that concerns have secured manufacturing facilities, and it would appear that every effort was to be made to supply the extraordinary demand expected as a result of the public interest which has been reflected in the various shows held since the beginning of the year.

The situation is rapidly becoming clarified. Road tests are under way in many sections of the country. It will still be some time before all the details will be worked out to the entire satisfac-

HERRESHOFF LIGHT CAR.**New Machine of the Cyclecar Type Designed by Well Known Automobile Man.**

As was stated in the last issue of The Automobile Journal, the Herreshoff Light Car Company has been organized, with factory in Troy, N. Y., for the production of the Herreshoff light car, designed by Charles Frederick Herreshoff, vice president of the Herreshoff Motor Company, Detroit. The machine will be marketed through the Herreshoff Motor Sales Company, with offices at 251-253 River street, Troy. The officers of the company are: President, Northrup R. Holmes; vice president, F. C. Pond; secretary, A. L. Johnson; treasurer, George N. Nay.

The machine is classified as a light car by the maker, although its piston displacement, the four-cylinder motor having bore of 2.375 inches and stroke of 3.25, is such as to place it in the true cyclecar class. The weight is 750 pounds, which is the dividing line between a true cyclecar and a light car. The wheelbase is 90 inches and the tread 44.

The motor is with the cylinders cast en bloc. The maker's rating is 16 horsepower. Cooling is by thermo-syphon. Lubrication is by splash with pump circulation. Ignition is by Atwater Kent Unisparker with storage battery. The carburetor is fed by gravity from a tank in the cowl dash. The machine is fitted with a mechanical starter operated by lever.

The clutch is a leather faced cone, with spring inserts, and the selective sliding gear transmission affords three forward speeds and reverse. Springs are of the cantilever type. Axles are of one-piece I beam section, semi-floating rear. The wire wheels carry 28 by three-inch tires.

The frame is of pressed steel, and the body, also of steel, is of streamline design, fitted with deep Turkish upholstery. The equipment includes a windshield, built into the body; top, two large electric searchlights with dimmers, electric rear lamp, complete set of tools, etc. The two passengers are seated side by side.

BREAKING ROADS WITH FALCON.**Virginia's Heaviest Snow Fall in 20 Years Affords Cyclecar an Interesting Test.**

The heaviest snow fall in more than 20 years recently swept down the historic Shenandoah valley, giving that portion of the Sunny South an appearance much more appropriate to Labrador. Incidentally, it afforded the Falcon Cycle-

car Company of Staunton, Va., an opportunity to subject one of its Falcon cyclecar chassis to a test which still further demonstrated its ability to cope with unusual conditions.

The factory, located on the windswept ridge of Richmond hill, overlooking the city, was surrounded by drifts; in many places about the level yard the snow lay 10 to 12 inches deep. It was wet and packed solidly the first day of the storm, sticking to the wheels and piling up in front of the car. It required nearly five minutes of steady bucking to break through a two-foot drift in front of the factory door, and during the entire morning the little machine broke trail around the factory and along the road to Waynesboro, with pounds of snow clinging to the wheels. Despite the apparent risk of jamming the exposed pulleys, there was no sign of belt trouble, both belts giving splendid traction and clearing out the pulleys without difficulty,

Falcon Test Chassis Breaking Out the Roads in Vicinity of Staunton, Va.

according to a letter from the company.

In the afternoon a sharp freeze turned the snow to a crisp, powdery condition, and through the half-broken wagon roads, the little Falcon climbed long grades and bucked newly formed drifts in such manner as to leave little room for doubting its ability. The fun ended when, turning out to avoid a wagon, a snow drift larger than the others confronted the driver, who elected to rush it at full speed. The machine went through the drift, but the crew decided it was time to return to the factory and get dried out. An accompanying illustration shows the little machine at work breaking out the roads.

It is pointed out in this connection that the roads in the vicinity of Staunton offer exceptional advantages for testing cars. The famous National Valley pike and the county pikes give combinations of long, level, perfectly surfaced

stretches for speed, and of grades which would try almost any machine in the country. Over-shadowing the city is Betsy Ball mountain, at one time held to be inaccessible to automobiles, but said to have been negotiated twice in one day by a Falcon chassis. Off the county pikes in any direction are roads of red clay, as sticky as the notorious Arkansas gumbo. It is under such road conditions that Falcon cyclecars are tested out before being placed on the market

WARD FROM MILWAUKEE.

Brief Details Concerning Machine Placed in the Market by Ward Butler.

In the absence of further details, it is impossible to classify the Ward cyclecar, made by the

Maker of Ward Directs Attention to Lack of Departure from Standard Automobile Lines.

Ward Cyclecar Company, not incorporated, Milwaukee, Wis., represented by Ward Butler, under the definitions recently adopted by the Cyclecar Manufacturers National Association, although from such information as is available it would appear that it was properly placed as a true cyclecar. The wheelbase is 96 inches and the tread 41. The two passengers are seated side by side.

Beyond stating that the motor is a Mack, and that the machine is fitted with a friction transmission and V belt drive, no further information has been made public regarding the mechanical details. It is pointed out, however, that the car is of standard underslung construction, with unusually long springs, 36 inches in the rear and 34 in front. This is held to give exceptionally easy riding qualities. Attention also is drawn to the lack of departure from standard automobile practise, insofar as the general appearance of the machine is concerned.

Mr. Butler states that the car shown has carried the driver and passenger a trifle over 50 miles an hour, and has taken rough country roads at a speed which would mean destruction to the larger machines. He adds that it has made from 35 to 50 miles to a gallon of gasoline.

IMP MAKES QUICK TIME.

Snow and Slush Offer an Exceptional Test Over Country Roads in New Jersey.

Another demonstration of the practicability of the light weight, narrow tread cyclecar was made March 4, when President H. C. Fairchild of the Cyclecar Distributing Company, Imp distributor in Newark, N. J., drove one of these little machines, made by the Imp Cyclecar Company, Auburn, Ind., from Newark to Paterson, N. J., a distance of 20 miles in 1:12:00. The roads were covered with snow and slush, as the result of the heavy storm which occurred in this section March 1-2—in many places to a depth of 1.5 feet.

Mr. Fairchild was accompanied by Harvey Batzle of Bloomfield, N. J., as passenger and observer. They left the office of the Newark Star at 1:40 in the afternoon and made the 10 miles between that city and Passaic in 42 minutes, despite conditions which had tied up traffic of all kinds for three days. The last 10 miles between Passaic and Paterson were covered in exactly one-half hour.

The total gasoline consumption was three quarts. In one place water hub deep was encountered, but neither this nor the snow and slush affected the action of the belt drive. At the conclusion of the run the little car was placed on exhibition at the Paterson show and attracted a great deal of attention.

HAWK APPEARS IN DETROIT.

Another Machine of the True Cyclecar Type Which Has Standard Automobile Tread.

As has been stated in these columns before, there are very few true cyclecars in this country which have standard automobile tread, but the list is increased by one by the appearance of the Hawk, the product of the Hawk Cyclecar Company, with factory at 256 Harmon street, Detroit. The officers of this concern are: President, Frank Slater; vice president and secretary, L. J. Philippart. The machine is a side-by-side seater with wheelbase of 100 inches, weighing approximately 600 pounds.

Attractive Roadster Design Utilized with A. C. Four-Cylinder Model.

The Hawk is equipped with a De Luxe two-cylinder, air-cooled, V type motor, having bore of 3.37 inches and stroke of 3.67, and being rated by the maker at 9-13 horsepower. Ignition is by Atwater Kent Unisparker and carburetion by a Schebler. Power transmission is by friction discs and belts. The wire wheels are fitted with 28 by three-inch tires. The equipment includes two gas searchlights, two oil side lamps, rear lamp, Prest-O-Lite tank, Sears-Cross speedometer, top, windshield, horn, tools, etc.

A. C. FROM NEW ORLEANS.

Practically Is Presented in Two Chassis Models and with Three Body Types.

Announcement was made in these columns recently of the organization of the Autocycle Company, New Orleans, La., which was to enter the cyclecar field, but the details of the product were not available at that time. It now appears that this is to be known as the A. C., and it will be presented in two chassis models with three body types.

The officers of the company are: President, Arthur B. LeCour; vice president and sales manager, W. J. Homer; secretary, George E. Dicks. The factory has been located on Girod street, and it is stated that this is fully equipped for a production capacity of 10 machines a day. The sales office is at 811 St. Charles street. Agency contracts are said to have been closed for 100 cars, and others are pending, which are expected to call for another 100.

Motor dimensions are not revealed by the maker, and the same holds true with respect to the weight, but from such information as is available, it would

appear that one of the A. C. chassis must be listed as a light car, while the other may be regarded as a true cyclecar. The former has a four-cylinder engine rated by the maker at 12 horsepower, and to this are fitted a roadster type of body, with seats arranged side by side, and a light delivery van. The other chassis has a two-cylinder V motor rated by the maker at 10 horsepower, and the bodies fitted thereto are

a tandem two-seater and a delivery van.

The four-cylinder chassis has wheelbase of 100 inches and 36-inch tread. The motor is water-cooled, and drive is by shaft. The frame is of pressed steel, suspended on full elliptic springs. The wire wheels carry 28 by 2.75-inch tires with the roadster and 28 by three with the delivery van. Equipment with either body includes electric lights and starter. A top and windshield may be had with the roadster at a slight extra charge.

The wheelbase and tread are the same with the two-cylinder chassis, but the motor is air-cooled and drive is by belt. In all other respects the specifications are identical with the other, except for the equipment, which does not include electric lights and starter.

The Continental Engineering Company, formerly located in Minneapolis, Minn., instead of Milwaukee, Wis., as previously stated in these columns, has been incorporated under the laws of Illinois and has opened headquarters at 1305 South Michigan avenue, Chicago. It will manufacture motors for cyclecars and light cars, under the direction and management of J. E. Pfeffer. It is also understood that this concern has been experimenting on a cyclecar to be produced in two-passenger and delivery car models.

Tandem Seating Cyclecar Body Fitted to A. C. Two-Cylinder Chassis.

JOHNSTON IS PRESIDENT.

White Company's New York Manager Heads Dealers' Association in That City.

The board of directors of the Automobile Dealers' Association, Inc., of New York City, met March 3, for the purpose of electing officers for the ensuing year, as follows: President, R. H. Johnston, manager of the White company's branch; vice president, Charles H. Larson, of the Oldsmobile agency; secretary and treasurer, Frank Eveland, Stevens-Duryea; general manager, Charles A. Stewart. Mr. Johnston succeeds Arthur M. Day, but the other officials were re-elected.

Very soon President Johnston will announce the personnel of a special committee to have in charge matters in connection with the large number of bills pending before the state legislature, and the proposed ordinances before the board of aldermen. Ever since the incorporation of the association, it has been very active in everything that would help to protect the automobile industry, and it is expected, by those who know Mr. Johnston best, that under his supervision, this work will be carried on even more vigorously in the future.

R. H. Johnston, President, Automobile Dealers' Association, New York City.

TROPHY DONOR OBJECTS.

Glidden Award Will Not Become a Prize for Longest Journey to Meeting.

Charles J. Glidden, donor of the trophy bearing his name, which has been one of the most noted automobile prizes in the world, is quoted as saying that he will not grant his permission to have the cup awarded to the person covering the

longest distance in attending the proposed mid-summer meeting of the American Automobile Association in the White mountains this year. The trophy is now held by the Metz Company, Waltham, Mass., it having been won by a team of three Metz cars during the national endurance run of 1913, from Minneapolis, Minn., to Glacier national park, Montana.

In view of the fact that the suggestion was made that this classic award be utilized in the manner stated above, it would appear that as yet no plans had been made to hold a national tour this year. It is expected that the Glidden trophy will be the chief award in a transcontinental tour to the Panama-Pacific exposition in 1915.

FIRST TO CROSS THE ANDES.

Johnson Martin Drives Buick Car from Coast to Coast in South America.

The Pan-American Union in Washington, D. C., was in receipt of a cablegram, Feb. 28, from Johnson Martin, formerly of Glen Ridge, N. J., and a Princeton football player of note, announcing his safe arrival in Santiago, Chile, after being the first to cross the Andes in an automobile. Martin left Buenos Aires, Argentina, Jan. 31, in a 25 horsepower Buick car, made by the Buick Motor Company, Flint, Mich. His cablegram read as follows:

Arrived safely this morning in Santiago. Highest altitude 13,000 feet. Everything snow above 11,000 feet. Terrible cold. Two weeks in mountains crossing Continental Divide. Feat never before accomplished. Great enthusiasm Santiago and Valparaiso.

JOHNSON MARTIN.

Martin graduated from Princeton in 1907 and has been representing the Buick car in South America since the organization of the General Motors Export Company, three years ago. He began a year ago to study the mountain trails for this attempt, and was accompanied on his trip by a mechanic. He also took along rope, tackle, shovels, picks, a small blasting outfit, two rolls of canvas about 100 feet in length, fitted with heavy ground spikes at either end (to be used as a temporary surface where the trail proved to be too slippery or too steep for traction), and other necessary paraphernalia.

He first crossed about 1000 miles of swamps and cattle country before reaching Mendoza, from which point he headed toward the famous Uspallata pass. The cablegram quoted above was the first word that had been received from him in this country since he left the city of Buenos Aires.

MECHANICAL NOTES FOR OWNERS.

Inexpensive and Easily Made Cabinet for Storing Small Material---Why Storage Batteries Fail---Home Made Oil Can Holder---Ford Magneto Hints.

PRACTICALLY every owner who attends to the repairs of his machine accumulates a collection of nuts, bolts, screws, etc., and usually these are kept in the drawer of the work bench or in a box. As a result, when a particular sized nut is wanted, the contents of the box is dumped on the bench or floor and a search made for the particular article. Such a method of storing parts makes for a decided loss of time, and many times new material is purchased when it is in stock.

In an accompanying illustration is shown a systematic method of storing the materials referred to, the plan being one adopted by a reader of The Automobile Journal. A predetermined number of cigar boxes, those holding 50 cigars for example, were obtained, and the covers removed. In the illustration 12 are shown.

A cabinet is made from white wood or other suitable material, it being constructed with partitions to retain the boxes as indicated. To each box is fitted a handle and a label is also pasted on the box. The handles were obtained at a hardware store for a few cents.

In arranging the boxes or drawers the owner placed cotter pins in one, lock washers in another, etc. Some of the boxes were sub-divided to retain different sized screws, for example. With each compartment marked, it is obvious that it is a simple matter to locate the material needed and quickly. The cabinet could be made sufficiently large to store the many useful parts and material necessary in the maintenance of the automobile.

WHY BATTERIES FAIL.

A complaint sometimes made by owners of cars equipped with electric motor starting and lighting systems is that the battery will not hold a charge. The Willard Storage Battery Company, maker of LBA batteries, explains that invariably this is caused by neglect, though not always on the part of the owner. It may be due to the fact that the machine stood for some time on the showroom floor and that a number of starts were made to demonstrate the action of the motor starter without operating the dynamo or replacing the current utilized. The owner of the car thus receives it with the battery in prac-

tically an exhausted condition, or he may use the machine in the city, making a large number of starts and without operating the dynamo at sufficient speed or long enough to properly charge the cells.

Under such conditions the battery should be removed from the car and given a long charge at a very low rate, one that will not cause it to heat above 100 degrees Fahrenheit at any time. This charging should be continued, testing the gravity of the electrolyte at frequent intervals by means of a hydrometer syringe. The length of the charge will depend upon the condition of the cells and may require two days or three weeks to bring them back to their normal capacity. Some motorists insist that the work be done over night or in 24 hours, and upon receiving the battery find that it is inefficient. Naturally, a complaint

Easily Constructed and Convenient Receptacle for Storing Nuts, Bolts, Screws, Etc.

is made to the agent of the car or the battery maker.

It is recommended that an ampere meter be inserted in the circuit to ascertain how much current is being sent to the cells by the generator at a speed equalling about 15 miles an hour car speed. It is stated that the dynamo should be generating at least the lamp load at 15 miles an hour. If not the system should be inspected.

Proper maintenance of the storage battery does not involve much labor. Test the electrolyte in each cell at least once or twice a month with a hydrometer syringe, and if found to read below 1.250, drive the car a long distance at a good rate of speed or run the motor with the machine standing idle until the electrolyte readings show 1.275 to 1.300 in each cell. If this

treatment fails, the battery should be removed from the car and carried to the expert for a long charge as previously explained. It is cheaper to

Home Made Oil Can Holder: A, Construction of Retaining Strip; B, Can in Place.

hire a battery while the old one is being rejuvenated than to take chances of injuring it by use in an improper condition.

CARE OF PETCOCKS.

Petcocks in the fuel line rarely give trouble other than leaking. When this condition exists, it may be remedied by tightening the locking nut or screw, and if this fails to effect a cure the construction should be disassembled as it may need grinding. As brass is generally employed, powdered glass or any fine abrasive should be utilized.

An odd accident to a fuel petcock came to the attention of the writer recently. The machine was a Ford, which has the petcock in the fuel line approximately under the front seats. In traversing a road a stone was thrown up by the road wheel, striking the lever of the petcock and shutting off the supply of fuel. Consequently, the motor stopped, which bothered the driver to locate the cause. Fortunately, he remembered the striking of the stone, made an investigation, and found the petcock closed. By tightening the screw member, the loose part was made proof against a similar accident.

OIL CAN HOLDER.

The oil can and the container used for carrying gasoline or other fuel utilized for priming, are generally stored in the tool box or carried in some other place where time is lost when their use is desired. A simple, practical and easily made can holder is shown in an accompanying illustration, it being noted by the writer on a Ford car.

The holder proper is shown at A. This consists of a strip of heavy spring brass, although any metal of sufficient stiffness may be employed.

Two slots were cut as indicated, but in making these the diameter of the spout should be considered, although by tapering the slot the holder could be employed with the average can.

By bending the metal at the points indicated by the dotted lines at A to the shape shown at B, a can is retained by the pressure of the slotted portion, which should be sprung slightly downward, as shown as the right in the illustration. By drilling four holes and utilizing machine screws or small bolts and nuts, the construction is secured to the motor pan just in front of the carburetor.

The cans are easily slipped into and out of position, and when their use is desired, the hood is lifted. Being in proximity to the motor, the heat of the engine keeps the fluids warm. This is an advantage in cool weather as the oil will flow readily. When one can is utilized for gasoline, its vaporizing point is raised, provided the motor has not become entirely cold.

FORD HOOD COVER.

Many owners display considerable ingenuity in constructing useful accessories for their machines, although able to purchase ready made devices. In an accompanying illustration is shown a home made hood cover for a model T Ford car, which the owner considers superior to the marketed article in that it is easily attached, and he states that it keeps the motor warm for a longer period than the purchased design. One of the interesting facts in connection with the hood is that the padding is made from a comforter which he used when he was in college.

Hood Cover for Model T Ford Car Constructed by Owner.

The material utilized was a fairly heavy brown duck, and this was made to conform to the shape of the hood as shown in sketch. To

retain the cover in place and to prevent any movement, a coil spring was fitted as indicated. The flap lifts upward and when thrown back as illustrated remains in position without any fastening. This, the owner states, saves time when operating on days when the weather is too mild for running the car with the flap down, as the flap may be lowered quickly when the machine is to be left for any length of time. The owner employs the car in his business and frequently makes long stops.

FORD MAGNETO HINTS.

The Hoyt Electrical Instrument Works, Penacook, N. H., in its instructions for utilizing its magnetometer, a device which is employed to test the Ford flywheel magneto, and which is described elsewhere in this issue, calls attention to some of the troubles that may be experienced with the magneto and their remedies.

Among those named is the accumulation of dirt under the contact plug of the magneto, which reduces its output, consequently affecting the operation of the motor at low speeds. When cleaning the plug, care should be taken to remove any foreign particles that may be in the hole.

End play of the crankshaft, due to worn main bearings, is held to be the most common cause of magneto inefficiency. It permits the magnets to rotate at a greater distance from the stationary coils than originally intended. The remedy for this is either to put in new bearings or take up the end play in the old ones so that the proper relation will be maintained between the magnets and the stationary coils.

Sometimes, little particles of metal will lodge between the ribbon terminals of the coils, forming sufficient ground to cut off some of the coils, or, sometimes, the oil will become impregnated with fine metallic dust that will ground the coils. By cleaning the coils thoroughly and renewing the oil the trouble is easily remedied.

To test stationary coils, use four or six dry cells connected in series. Attach one terminal of the battery to the insulated plug in the top of the magneto and the other battery terminal to the connection where the last coil is grounded to the plate. Then, with a piece of soft iron, touch the iron core of each coil to see if there is a good "pull". If trouble is found to exist, try out the coils one at a time by touching the battery terminal on the terminal of the first coil and determining the "pull". Then on the second, repeating the operation until the grounded coil is located.

Relative to weak magnets: This trouble is not common. As they are liable to have cracks in them, and few repair shops have facilities for properly recharging them, it will be found, in the majority of cases, better economy to replace faulty ones with new, especially as the cost is not great.

MAGNETO SUGGESTION.

A repairman who has had considerable experience with magnetos makes the following suggestion: Examine the magneto from time to time to note if any of the screws, particularly those holding the magnets to the pole pieces, be loose. The constant vibration may loosen some of these, which should be kept tight to prevent foreign elements working into the instrument and impairing its efficiency.

ANNEALING WIRE.

It may happen that a piece of soft wire is needed to make a repair and the tool box contains only hard or spring wire. This may easily be made flexible by annealing. The process is simple. Hold the wire in a naked flame until it becomes red hot, then allow it to cool gradually.

KEROSENE ON WORLD TRIP.

Kohl Now Touring the Holy Land—Saves Much Money by Shunning Gasoline.

According to information received March 1, from Edward P. Kohl, the University of Wisconsin student, who is enjoying a world tour in a Henderson car, made by the Henderson Motor Car Company, Indianapolis, Ind., the party is now in the Holy Land, having left Egypt a few days previous to that time. The car is fitted with a Harroun carburetor, produced by the Harroun Company, also of Indianapolis, and burns kerosene. The entire trip has been covered with kerosene as fuel.

Kohl left Indianapolis in August, and in a letter mailed from Vienna, he stated that he was saving about \$10 every time his 40-gallon fuel tank was filled. At that time he had visited the British Isles, Germany, France, Holland, Russia and Austria, in which countries he found that the price of gasoline varied from 40 to 60 cents a gallon, while he was able to purchase kerosene for about 16 cents.

It may be added that the machine is fitted with an Eisemann magneto, made by the Eisemann Magneto Company, New York City.

 gress of March 3rd, 1879.

SAFETY FIRST.

While it is absolutely true that the automobile is nowhere near so dangerous as the publication of statistics would seem to imply, there is abundant reason why automobile accidents should be much less frequent. The compilation of these statistics has been impelled by the apparent increase in the number of reckless drivers, although, as a matter of fact, the percentage of those who operate their machines without due regard for the rights of other users of the highways is exceedingly small.

The reckless driver is a distinct menace. Not only does he endanger the lives of other highway users—pedestrians, occupants of horse drawn vehicles and the vast majority of law abiding motorists—but his existence is harmful to the industry. Much of the drastic legislation

which has been enacted and many of the bills proposed each year have their inception in an attempt to curb this small minority. And, despite the accumulation of laws, their ineffectual administration tends to cause greater hardship upon those who honestly seek to avoid accident, without any appreciable effect upon the real offenders.

Public opinion is a valuable asset. Societies have been organized for the purpose of influencing public opinion in a manner not calculated to benefit the automobile industry. That organized motorists have seen fit to meet this agitation in a practical manner is worthy of special commendation. The "Safety First" campaign, now in process of inauguration, is one which should, and undoubtedly will, receive the heartiest co-operation by manufacturers, dealers and owners. It is a movement which will mean much to the industry as a whole, and once the foundation has been laid, it ought to be less difficult to secure the proper enforcement of such legislation as has reached the statute books, when it will be found that the need for additional regulation is at least open to question.

THE CALIFORNIA DECISION.

The position taken by the California supreme court, as set forth elsewhere in this issue, is somewhat new. United States courts have held that when the fee is made larger than is sufficient to meet the expense of administering the law, it becomes a tax. Other state courts, notably in Mississippi and Ohio, have decided against the constitutionality of laws having provisions similar to those of the California statute, and on the ground that the fees thus provided took the form of a tax.

It is of interest in this connection to note the opinion made public by Sidney P. Osborn, secretary of state for Arizona, in which he holds that the law requiring the registration of motor vehicles in that commonwealth is manifestly unconstitutional, because the fees result in the collection of far more money than is necessary to administer the law, and, therefore, in double taxation. The new California law makes no provision for exempting automobiles from taxation in other ways, and it would seem that the supreme court would have had little trouble in discovering that double taxation existed.

GRAY & DAVIS FACTORY A MODEL PLANT.

Has Three Acres of Floor Space, Employs 600 Men and Manufactures Over 300 Systems a Day--Well Ventilated, and Sanitary Conditions Are Excellent.

SOME idea of the remarkable growth of the electric lighting and motor starting industry may be obtained from the statement that the new factory of Gray & Davis, Inc., Cambridge, Mass., averages an output of 320 systems each working day, or approximately 100,000 a year. Such a large production not only requires the latest manufacturing facilities, but the machinery and departments must be so arranged that the minimum of time is wasted in converting the raw material into a finished product.

The present magnitude of the Gray & Davis business is due to the executive ability of President William Gray. His policy of perfecting an article and incorporating only the best of material and workmanship, or in other words, maintaining a high standard, has made Gray & Davis a leading manufacturer of lighting and motor starting equipment. In the construction of the new factory no detail was too small for Mr. Gray's attention. As a result the new plant is not only a beautiful structure, but one of the finest business buildings in the country.

The plant itself occupies the centre of a spacious plot facing the Charles river, between which and the factory is 150 feet of lawn and parkway. The main building is 381 feet six inches in length, with a width of 81 feet for the first story and 61 for the other four. The total floor area is nearly 140,000 square feet, or approximately three acres. There is an ell in the rear, 36 by 62 feet, this running through the full height of the building and containing the elevator tower, stair tower, tool, store, locker and wash rooms. For the last three uses mezzanine floors are interposed above the first floor. This

portion of the structure is framed in steel.

The material employed is reinforced concrete. The ornamental end bays are faced with brick, while the sub-structure is concrete. Those portions of the wall between the pilasters which are not occupied with the steel sash windows are of concrete panelled with tapestry brick. There is no basement. The main floor is laid directly upon the fill without the use of forms, and is practically a part of the ground. The piers were carried down to a solid footing at a depth of 12 feet. All of the columns are cylindrical, with mushroom tops, giving a particularly effective appearance, as well as providing maximum strength. The columns are of reinforced concrete, whereas the piers below them, being supported by the

hard fill and thus subject to compression only, are plain concrete without steel reinforcement. The wall columns are rectangular in section, carrying under each floor a corbel for giving the floor slab that local support which it receives from the mushroom

New Gray & Davis Factory, Having a Total Floor Space of 140,000 Square Feet, and Utilized Exclusively for the Manufacture of Electric Lighting and Motor Starting Systems.

heads of the interior columns mentioned.

All floors above the first are 8.5 inches thick, these slabs measuring 20 feet square to the centres of the columns and being built without beams or girders of any kind. The top layer is about one inch of granolithic finish, which was laid some time after the structure of the floor. The large open space provided by the wide spacing of the columns makes it possible to locate machinery almost without regard to interference from this source.

Between wall columns a reinforced concrete beam, 36 by eight inches, was cast in each bay. This is cast into slots left in the pilasters, thus making an expansion joint at each end of the

At Left, Stairway and Entrances to the Offices from the Lobby; at Right, Corridor of Main Offices from Entrance.

beam, a thoughtful provision against the opening of disconcerting fissures in the attractive tapestry brick exterior. These beams form a portion of the outside wall of the building. As the lower edge of the beam is in the same plane as the ceiling, it will be noted that this beam extends well above the floor level and that the floor is dependent from it. By this means the windows are run clear up to the ceiling level and an absolute maximum of lighting is obtained. The window area is 70 per cent. of the entire wall area.

Large Window Area.

Steel sash is utilized throughout, in each case so arranged that 33 per cent. of the window area is adjustable for ventilation. In the case of the executive office, on the second floor, the operating portion of the sash is double hung, so that it may be handled as ordinary windows. In the manufacturing part of the building each ventilating sash is pivoted at the centre. The area available for ventilation thus figures out 21 per cent. of the entire wall area of the building. Natural ventilation alone is provided by large num-

ber of windows, no blower system being needed.

All pipe sleeves are arranged through the different floors. Instead of using a tin sleeve or one of galvanized iron, wrought iron pipe has been utilized in every case. These have been left three inches high above the floor as a precaution against leakage of water into a lower floor at any time when water may lie upon an operating floor, from the breakage of a sprinkler, from water thrown on a fire, or from washing down a floor, for example.

All conduits for electric service, including lighting and power, are concealed in the floors. This eliminates loose wiring and conduces toward appearance and freedom from trouble. Power outlets, with suitable plugs, are located in both ceilings and floors at convenient intervals, so that power will be available for any machine within easy distance and with a minimum of trouble. A somewhat similar arrangement is the location of inserts in the concrete, four feet apart in both directions over the entire area of the ceilings in the manufacturing department. This makes it possible to attach shaft hangers or

At Left, General View of the Heavy Machine Shop; Centre, One of the Banks of Drills; Right, Heat Treating Room.

other pendent devices at any place where they may be needed.

The system of heating is very ingenious, it being stated that there are but two other plants utilizing the method. The unusual window area made it necessary to use a large amount of radiation surface for heating, and to have provided this in the form of coils and radiators along the walls would have involved a great many large units. It was decided, therefore, to use the sprinkler piping in the ceiling as an auxiliary heating surface. This, of course, necessitated the use of hot water as a heating medium, with its ready control and adaptability to changing climatic conditions.

To guard the sprinkler heads or to prevent fusing, they were placed on offsets about a foot long. The water in these offsets is, of course, not in circulation, whereas the system of piping is so arranged that continuous circulation is kept up from the riser on one side of the building to the return on the other in each of several sections. In this way the distribution of heat is kept uniform all over the building, while at the same

time the pipes, being continually traversed by moving water, cannot become clogged in any place.

Ready Delivery of Material.

The stock, store and toolrooms, located near the centre of the east wall on each floor, are in the same ell in which are located the elevator and stairs, and hence are ready of access for the delivery of material. In working out the locker rooms, it has already been mentioned that structural steel was used as a frame work. In order that the columns might not interfere in any way with the free use of the locker rooms, it was arranged to use small columns, each made of two steel angles back to back, these being located in each case at the end of a row of lockers where they are completely out of the way and do not block the alley space. This provides a somewhat narrower column and beam spacing than might otherwise have been chosen, but worked very well with small I beams as the basis for the floor structure.

The offices are handsomely finished. The partitions are solid mahogany and glass, reach-

At Left, Testing Department; Generators Being Subjected to a Duration Test; Centre, Testing Starting Motors; at Right, Tool Department in Which All Tools and Jigs Are Made.

ing a height of about eight feet above the floor. The windows in this section are double hung, as previously referred to. The radiators are of a very pleasing design, taking the place of the coils of piping in the factory. The furniture, which was especially manufactured, matches the partitions and decorations.

Luxurious Offices.

Mr. Gray's office and the directors' room adjoining, have large open fire places, and the floors are laid in red tile, covered by rugs. The windows are screened by silk velour curtains and all of the appointments are in keeping with the luxurious surroundings. The lobby on the first floor opens directly upon a broad staircase with easy flight, which lands near the centre of the offices, and permits ready access to all parts. On the first floor is the retail sales department. Back of the private offices and separated from the main corridor by a wrought iron rail, the general office, occupied by clerks and stenographers, covers the entire width of the building. The broad corridor, running down the centre from the head of the staircase to the door leading into the manufacturing department, and limited by glass and mahogany partitions on either

side, passes on through the general office, but without partitions, the location of the desks serving as a general outline to its course.

At the four corners of the main building wrought iron balconies have been added to the second floor as ornamentation. Painted a bronze green, they add a touch of color which blends with the gray of the concrete and the mottled red and purple of the tapestry brick. The marquise has the same color scheme as the balconies and adds a further touch of ornateness to the east end of the structure.

The routine of the factory consists of six main operations, receiving, machining, stocking, assembling, testing and shipping. All material, including office supplies, etc., passes through a door at one end and a record is made. The entire ground floor is utilized for machining, milling, grinding, drilling, etc. The machined parts go to the next floor, where they are stocked in steel trays arranged in numbered racks and entered in a card index, from which can be quickly ascertained the exact quantity in stock. In filling orders the required parts are withdrawn from the stockroom and sent to the assembling department. The system used is excellent.

At Left, Dynamoes After Being Tested and Ready for Assembling; at Right, Shipping Department.

The finished material, such as motors and generators, is then passed to the testing department, where individual, duration and abusive tests are made, the results being so recorded that permanent data are always available. Having met all requirements the machines are returned to the ground floor and shipped directly to the railroad siding.

Location of Departments.

The machine shop on the first floor occupies the full length of the building with the exception of the lobby at one end. The machines are arranged in banks, the gear cutters and shapers, automatics, turret and chuck lathes being at one end and the grinding, stamping and buffing at the other. The second floor is divided, the stock-room occupying one-half and the offices the other portion. On the third floor is the testing department. All dynamos are run in for several hours on a long bench and at constant speed. The output, etc., is entered on record cards attached to each machine, and these cards are filed. The motors are subjected to severe tests. Assembling is done on this floor, the work immediately preceding the testing. The fifth or top floor is divided into four main sections, tool making and winding shop, experimental laboratories with engineers' offices, drawing room and restaurant. The tool department is adjacent to the elevator and as the tool supply on each floor is in the rear tower containing the elevator, tools can be transferred quickly from or to any floor. Jigs are used wherever possible.

Columns Numbered.

Throughout the plant all columns are numbered to indicate the position of the machines. Thus 5-13 indicates the fifth floor and the 13th bay. A similar method of numbering the stock-rooms bays is utilized. Each rack is numbered and the shelves carry a letter. The wood trays employed to accommodate the parts in the process of manufacture are all made in the carpenter shop.

Owing to the rather isolated situation of the plant the restaurant is popular with the employees. It has a seating capacity for 80 persons, but its uses extend much further. Orders can be received from any floor by telephone and at lunch time food is sent down by the elevator.

Two boilers are utilized, one supplying the hot water, the other furnishing steam for cleaning jets in the factory and also for the restaurant. All lavatories, toilets and cloak rooms are located in the rear extension, which has intermediate floors, providing the necessary area. The rack and separate coat hanger method is employed, it being thought more sanitary than the

individual locker. The toilets are separate from the cloak room, so that the latter may be locked during working hours. Entrance can only be made by application to the foreman of the room for the key.

Protection for Employees.

Large wash rooms are provided on every floor. A hospital provided with equipment for dealing with any accident is on the fourth floor and a qualified physician is always in attendance. In addition a bed is maintained in the Boston City Hospital. Opportunity for accident has been reduced to a minimum, rails being provided at dangerous points and all pulleys about machines are guarded. About 600 men are constantly employed.

The Gray & Davis factory is looked upon as a show building and visitors are cordially welcomed and shown through the plant by a competent guide.

BOSCH RACING VICTORIES.

Magnetos and Plugs of This Make Play Prominent Part in California Events.

Because of the late arrival of information concerning the running of the Vanderbilt Cup and Grand Prize races in California, last month, little space was available in the last issue for calling attention to the good work accomplished by the accessories fitted to the winning machines.

The Bosch Magneto Company, New York City, represented in Boston as New England distributor by the Motor Parts Company, 187 Columbus avenue, is calling attention to adverse conditions under which the complete ignition performs its functions when fitted to machines taking part in races of this character. The high speed, terrific external heat and excessive vibration are extremely trying upon the magneto, but the spark plugs have even more trying conditions to contend with, for they must withstand the excessive heat generated within the cylinder walls! meet the varying degrees of pressure created by the action of the pistons, withstand the overdose of oil continually administered, and with all this, give a clear path for the intense spark of the high-tension magneto.

It is significant that the drivers competing in the races named selected Bosch magnetos in all cases and Bosch plugs in nearly all. Since De Palma in a Mercedes created a new record for the Vanderbilt Cup event, and Pullen in a Mercer for the Grand Prize, Bosch magnetos and plugs also share in these record breaking performances.

WITH THE MOTORING INTERESTS ABROAD.

Well Known British Engineer Explains Interesting Phenomenon Respecting the Movement of Pistons—Features of South African Regulations—Other News.

MOTORISTS generally undoubtedly will be interested in the explanation of a most interesting and peculiar phenomenon in connection with the periodic movement of pistons, which was made in the Autocar, a British motoring publication, recently, as the result of an inquiry raised by one of its readers. The correspondence in question is reproduced herewith, as well as the diagrams utilized in explaining the point.

Eric W. Walford, a prominent English automobile engineer, was discussing the subject of "Lighter Pistons", a contribution purely techni-

clearly brought out by the following communication:

I do try to follow the experts in their expositions upon various phases of the internal combustion engine as admitted to your pages, but confess to being absolutely fogged by Eric W. Walford in his article upon "Lighter Pistons", in last week's issue. He bases a most important argument upon the statements:

"The piston travels faster during the top half of the revolution of the crank pin than during the lower", and, "the ascending piston is further from the mid-position than the descending piston is."

If Mr. Walford's engine had stopped at the position shown by the dotted lines in the diagram, and the crankshaft were reversed by hand, so that the ascending piston became the descending one, it would have less distance to go to get back to its original starting point than it covered in getting away from it!

I am also completely puzzled as to how the piston can travel faster during the top half of the revolution of the crankpin than during the lower.

The movements of the pistons being controlled by the movements of the crankpins, how can their speeds differ? And, if I suddenly turned the engine upside down, then it ought to have an immediate effect upon the relative speed of the two pistons! MYSTIFIED.

In making reply to this communication, Mr. Walford utilized the drawing at the right of the sketch to illustrate the point as still further amplified. A little study of this reply, in connection with the diagram, should enable the reader to understand the existence of the phenomenon, even if he is unable to explain the reason therefor. Mr. Walford's explanation follows:

One can understand your correspondent not quite comprehending the periodic movement of the piston from the brief reference to the matter in my article in the Autocar, as it really requires a special diagram to make the point clear, and such a diagram was not merited by the subject of the article.

I was briefly referring to a point which is well known to experienced engineers, and will probably be comprehensible to most people with a fair amount of technical knowledge. To the lay reader, however, the point may be of somewhat difficult comprehension, but I suggest to your correspondent that he should cut strips of cardboard and gum two pieces parallel to one another on a board so as to represent the cylinder walls. Sliding between these must be a square piece of card to correspond to a piston, and a crank and connecting rod can be added, being joined together by paper fasteners, pins, or eyelets. The shorter the connecting rod is made the more pronounced will be the result.

Mark a circle on the table to correspond to the path of the crankpin, and divide this into 24 equal parts. Then start at the bottom dead centre and move the crank pin to the first mark, i. e., a 24th of a revolution, 15 degrees, then mark the point to which the piston has ascended, and so on through the whole travel of the piston, so that one gets 24 positions, somewhat as shown in the accompanying diagram. Your correspondent will then see that the spaces between these marks do not increase equally to the maximum and then decrease.

Briefly, it may be stated that, as the piston moves towards the crankshaft, it travels farther during the first 30 degrees of crank rotation than during the last 30 degrees.

On the accompanying diagram the crank obviously moves through the same angle from points 1 to 4 as it

Diagrams Illustrating Interesting Phenomenon: At Left, Ascending Piston Is Further from Mid-Position Than Descending Piston; at Right, Various Positions Plotted to Still Further Bring Out the Point.

cal in character, during which he called attention to the diagram at the left in the accompanying sketch, which was drawn to cover other points than that which was raised. It shows two pistons and cranks in exactly the same horizontal plane, and Mr. Walford made the point that when the crankpins are in an intermediate position, as indicated by the dotted lines, the ascending piston is further from the mid-position than the descending one. The point raised is very

does from 13 to 16. On the other hand, if one compares the distance from 1 to 4 with that from 13 to 16 on the vertical line, the greater length of the latter is at once apparent. Of course, whether the engine is upside down or not the effect is just the same. A little experimenting with a cardboard model will make this point quite clear, although at first it seems a paradox.

ERIC W. WALFORD.

CLUSTER SEATING ARRANGEMENT.

Ingenious Method Evolved by Australian Designer for Carrying Four in a Roadster.

As has been indicated to some length recently in these columns, foreign coach makers are prone to devote no little attention to the production of motor car bodies which may be considered out of the ordinary, to say the least. Often these designs are held to be the result of an attempt to secure something which possesses particular artistic merit. In the accompanying illustration, however, is presented the result of efforts on the part of an Australian designer to produce economy, in that it is maintained that the body shown can be constructed at the same cost as an ordinary two-seater.

It may be added, in this connection, that several European designers have produced three-seated bodies for so-called cycle-cars or light cars, which include some of the features presented in this design. One of these was exhibited recently in the Importers' Salon at the Hotel Astor in New York City, fitted to a Bugatti chassis.

In addition to the low first cost effected by the design presented herewith, it is maintained that easier riding qualities are produced, since the rear passengers are located further forward than usual with four-seated bodies. The width of the body does not exceed that of the ordinary roadster.

SOUTH AFRICAN LEGISLATION.

Motoring Laws in Four Provinces Indicate Important Growth in Use of Cars.

Because of the numerous American automobiles, both passenger and commercial vehicles, which have been sold in South Africa, it will prove of interest to note that motoring laws recently enacted went into force in the provinces of Cape Colony, Transvaal, Natal and Orange Free State, Jan. 1. It would seem that the ex-

perience of other nations in handling this difficult subject would have made it possible for the provincial councils involved to have enacted uniform ordinances covering this matter, but it will be seen that such was not the case.

In all four provinces it is required that both cars and drivers shall be licensed. With respect to the latter, the applicant must submit to an examination as to car control and observance of the usual traffic rules. Wherever possible, it is provided that the examining board shall include one member or more from a recognized automobile club. The driver's license in Cape Colony and Orange Free State is 20 shillings; in the Transvaal, 10 shillings, and in Natal, not exceeding 10 shillings. In the last named instance the exact amount is yet to be fixed by borough by-law.

In Orange Free State the car license is perpetual at 40 shillings a car, irrespective of size or horsepower. In Natal, the amount must not ex-

Example of Cluster Seating Arrangement Devised by Australian Designer for Accommodating Four Passengers in a Roadster.

ceed £3 a car, the exact amount to be fixed by the same authority as that of the driver's license, and this must be paid annually. In Cape Colony there is a sliding scale, with annual fees, as follows: Cars weighing 1500 pounds and under, 30 shillings; 1500-2500 pounds, 40s; 2500-4000 pounds, 60s; 4000-6000 pounds, 100s; over 6000 pounds, £10. In Transvaal there is a basic charge of £2 a car, annually, plus one shilling a horsepower and two shillings for each 100 pounds in weight.

Provision also has been made for licensing dealers and manufacturers, although there are none of the latter as yet, in Cape Colony, Transvaal and Orange Free State, the annual fee being £10. In Natal the dealer's license fee must not exceed £3. It may be added that these fees are in addition to the regular license fee common to all traders in the country. In consideration of this extra fee, the dealer is permitted to operate

cars in trial for prospective purchasers, the period during which any one car may be so run in the Transvaal being one month.

The provisions for touring would appear to be about the same as in the United States. Cars registered in the other provinces may be operated in Natal without further registration. In Cape Colony and Transvaal, such licenses are good for three months in any one calendar year, and in Orange Free State, for a continuous period of one month. No provision is made for cars owned outside the Union of South Africa.

The Transvaal ordinance has no speed limit, except in special circumstances or within certain defined areas, and permits the motorist to drive with due regard for the nature, condition and use of the road, and to the amount of traffic which is actually thereon at the time. The Cape Colony and Natal laws have a maximum speed limit of 30 miles an hour, and Orange Free State, of 20.

There are a number of other provisions, of course, particularly with reference to commercial vehicles, these having to do with the weight permitted to each inch of tire width, use of trailers, etc. In the main, however, the constructional details demanded for pleasure cars do not differ materially from those required elsewhere. In each province the funds are to be devoted to the construction and maintenance of roads.

GRAND PRIX ENTRANTS.

Thirty-Nine Cars Will Represent Six Nations in French Event July 4.

Entries at the original fee for the French Grand Prix closed last month, and it is found that 14 manufacturers, in six countries, are to be represented by 39 cars. Additional machines may be listed at double fees until March 31. The race will be held July 4, over the Circuit de Lyons, a 23.5-mile course, which will be covered 20 times, making a total distance of approximately 470 miles. The entrants comprise the following, listed as to country, number, make of machine and driver:

French—1, Alda, Tabuteau; 2, Peugeot, Boillot; 3, Peugeot, Goux; 4, Peugeot, Rigal; 18, Alda, unnamed; 24, Alda, unnamed; 28, Th. Schneider, Champoiseau; 29, Th. Schneider, Croquet; 30, Th. Schneider, Gabriel; 31, Delage, Babirot; 32, Delage, Guyot; 33, Delage, Thomas.

Italian—8, Nazzaro, Nazzaro; 17, Caesar, unnamed; 19, Aquila-Italiana, Marsaglia; 20, Aquila-Italiana, d'Argentina; 21, Aquila-Italiana, unnamed; 34, Nazzaro, unnamed; 37, Fiat, Wagner; 38, Fiat, Cagno; 39, Fiat, unnamed.

German—9, Opel, Joerns; 10, Opel, unnamed; 11, Opel, unnamed; 12, Mercedes, Lautenschlager; 13, Mercedes, Pilette; 14, Mercedes, Salzer; 15, Mercedes, Nagel; 16, Mercedes, Seller.

English—5, Sunbeam, Resta; 6, Sunbeam, Chassagne;

7, Sunbeam, Lee Guinness; 25, Vauxhall, unnamed; 26, Vauxhall, unnamed; 27, Vauxhall, unnamed.

Swiss—35, Picard-Pictet, unnamed; 36, Picard-Pictet, unnamed.

Belgian—22, Nagant, unnamed; 23, Nagant, unnamed.

MORE BRITISH RECORDS.

Bentley in a D. F. P. Secures Marks in Class B, Lower Than American Figures.

While it is not exactly proper to compare the records made under the British class B with those of the lowest classification in America, 160 cubic inches and under, it is true that W. O. Bentley recently secured records on Brooklands track, Weybridge, England, which are lower than the speedway marks held in this country by cars of the above classification. The maximum piston displacement permitted under the British class B is 2048 cc (about 125 cubic inches).

Bentley covered a half-mile in 20.07, a kilometer in 25.06, one mile in 41.05, two miles in 1:23.41, five miles in 3:33.13 and 10 miles in 7:07.09. The best records in this country, corresponding in any measure to these, were made by Frank Witt in a Flanders in the 160 cubic inches class at Indianapolis, Nov. 13, 1911, when he drove a mile in 56.80, and five miles in 4:22.08, and by Robert Evans in a Flanders at the same place the same day, when he drove 10 miles in 8:53.97.

NEWS NOTES FROM ABROAD.

The first automobile tour in Morocco took place recently, when 11 machines started from Casablanca. Part of the trip was over the plain of Ben Guerir, where only a year ago Col. Mangin fought a hard battle, while marching on Marrakech.

A special competition of four-wheel drive tractors for military purposes was begun before French army officials, March 2, and will be continued until March 20. At the completion of the tests the vehicles will be entirely dismantled at the artillery shops in Vincennes.

It has definitely been decided to hold the 1914 Tourist Trophy race on the Isle of Man, June 10-11. The Royal Automobile Club of Great Britain also has decided to hold a light car race over the same course in May. This event will be limited to cars that have piston displacement of 1400 cc (approximately 85 cubic inches).

The Warsaw Automobile Club, Warsaw, Poland, is organizing a reliability trial for June 26-29, to determine the type of car best suited to the Polish roads. The total distance covered will be about 1139.5 versts (about 755 miles), all on metal roads, with the exception of about 38 versts (25 miles). The event will be international in character and entries will be received until May 25, addressed to Tow, Automobilistow, Krolewstwa Polskiego, 6, Czysza, Warsaw.

In connection with the use of the international touring pass in Russia, it is explained that the pass is not inspected either at the customs office or by the police, but it is the duty of the owner to take his car and pass to the police office for registration, stating what towns he wishes to visit. The police then notify every police office in the districts to be traversed, and nothing further need be done for six months. There is no charge for this registration, but failure to observe the formalities makes the owner liable to a fine for driving an unregistered car and subjects him to the necessity for taking out a Russian license.

Cadillac Clutch—Young Reader, Lawrence, Mass.

Please give me complete information concerning the lining of the leather faced cone clutch such as used on the Cadillac.

If it be necessary to reface the clutch its removal from the car will be necessary. While the model of the machine was not given, the writer believes that the drawing at Fig. 2, which illustrates the components of the 1912 Cadillac, will be of service in dismantling clutch mechanism.

To remove the main clutch and universal joint, displace the pedal shaft E, the eight screws F F, and close together the sleeves G and H. The joint is then removable. Next displace nuts C C and the springs B, which will permit of taking out the clutch disc. The clutch bushing may be withdrawn by removing the cap L, cotter pin M, and the right hand threaded nut N. In reassembling the clutch, turn the nut N by hand until it brings up lightly, then back it off until the cotter pin can be inserted.

If the old facing can be removed without breaking it up, it may be utilized as a pattern for a new one. To make a pattern take a large sheet of paper and lay out the clutch to exact size, making sure that faces are at proper angle.

At Fig. 1 is a diagram for determining the size of the new clutch leather. Draw a line through the centre of the hub and parallel with it, this being represented by the line A-B in the drawing. Continue the angle of the cone by straight lines meeting at a point in the centre line. Then using this point as a centre and the distances from B to C and B to D as radii, describe the circles E G and F H. The distance from E to G must equal the largest circumference of the cone so the ends will butt together, or it may be advisable to make the strip a little longer than necessary and allow for fitting. The pattern thus obtained may be used to cut the new leather.

Before riveting in place the leather should be made as pliable as possible with oil, although there exists some difference of opinion among repairmen regarding this practise. Some advocate soaking it in water and applying it wet, so that when it dries it will shrink and hug the cone closer, while others apply it dry and oil it after it is placed. In the opinion of the writer the water method is likely to result in the leather pulling away from the rivets, while oiling the material after application is apt to cause expansion and an uneven surface. When the leather is oiled before application it is soft, elastic and pliable, and if properly fitted there will be no trouble in the material becoming loose or so closely engaged that it will burst from its fastenings.

There is also a difference of opinion as to fit-

Fig. 1—Method of Making a Pattern or Determining Size of New Clutch Leather.

ting the leather. A good method, however, is to place the leather in position at one end and hold it with small clamps. The holes are then drilled and the leather riveted in place, care being taken that the holes for the rivet heads are countersunk deep enough so that the metal will be well below the surface of the leather. After the end is securely fastened the leather is pulled tightly around the cone to the next point of fastening, the facing being stretched by a clamp, the holes drilled and the rivets applied, the operation being repeated from one point of attachment on the outer circumference of the cone to the next. This method of fitting the facing insures that it will hug the cone closely, instead of standing away between the rivets, as is the case when all holes are drilled in the leather at the same time.

When the facing is applied it should be trued in a lathe by taking a light cut off the surface,

or the high spots may be rubbed off by hand with sandpaper, a piece of glass or a coarse file. The best material for cone facing is good oak bark tanned sole leather or belting, though hemlock tanned is often used with good results. The former material possesses most of the qualities of elasticity, durability and the degree of friction adhesion required. The maker of the Cadillac recommends the use of neatsfoot oil only and the use of it sparingly.

The clutch will have to be adjusted after replacement. To determine if the main member A (Fig. 2) seats properly, grasp the clutch pedal, and if it can be moved back and forth approximately an inch or more with the application of moderate pressure and without starting to release the clutch, it may be assumed to be correct.

Sometimes the failure of the clutch to seat firmly is due to the stay rod D, and it may be

Fig. 2—Sectional View of Cadillac Clutch with Components Lettered to Aid in Its Dismantling and Re-assembly.

necessary to lengthen this member, which is accomplished by means of the nut O. However, if the stay rod is so adjusted that it will permit the clutch to seat firmly, but the latter does not do so on account of insufficient spring tension, the tension should be increased by turning the nuts C on the six springs B B. A little study of the drawing at Fig. 2 should enable one to dismantle and reassemble the clutch components.

Magneto Trouble—H. K. C., Camden, N. J.

Referring to No. 1680 in the Dec. 25 issue, in which "Information" states that in moving his switch lever from the magneto side to "off", the motor sometimes continues to run, could not the trouble be carbon in the cylinders or a hot engine? I have a single-cylinder car and frequently after throwing off the switch the motor will continue to run until I shut off the fuel. The ignition is battery only.

The presence of carbon in sufficient quantities may cause ignition of the mixture, but generally it is preignition of the charge as particles of

points of the carbon become incandescent. An overheated motor will require the shutting off of the supply of fuel to bring it to a stop as above stated.

The trouble referred to by "Information" was evidently caused by the switch not closing properly, as it was stated to occur when operating on the magneto. It should be remembered that with magneto ignition the primary current is short circuited or diverted from the secondary winding by closing the circuit. This is also termed grounding.

Cylinder Scored—E. F. C., Milwaukee, Wis.

In accordance with instructions given me I looked over the timing of the valves of my motor. I also set the timer so that when the spark lever is fully retarded the engine cannot back fire. Is this correct? As I did not locate my trouble I decided to dismantle the motor and found that the wristpin of one cylinder had worked loose and had worn a groove in the cylinder. The groove is too deep to permit of reboring as the cylinder has been rebored. Is there any remedy for filling in the groove that you could suggest? The motor, as near as I can make out, is an air-cooled Corbin. It has T head (?) cylinders with the inlet over the outlet valves. Any information you can supply will be appreciated.

The timer should be set with the piston of the cylinder just about to begin the firing stroke when contact is made between the roller of the commutator and its block, and with the spark lever fully retarded. If the engine idles and operates properly with the setting stated, and without back firing, it is presumably correct.

As far as the writer knows there is no satisfactory method of repairing a scored cylinder other than grinding or reboring. The only remedy would be to fit a new cylinder. If this is done, care should be taken to fit a piston, as it is very probable that the old one would not be of proper dimensions.

As the model of car is not given the timing cannot be given, but it is possible that the flywheel may be marked with the opening and closing points of the valves. If the number of the motor or model can be ascertained, the American Hardware Company, New Britain, Conn., may be able to supply information, as the Corbin Motor Vehicle Corporation was a subsidiary of the concern. The Corbin car has not been manufactured for some time.

Marking Flywheel—A. H. K., Providence, R. I.

I have a second hand car, the four-cylinder motor of which has a plain flywheel; that is, the opening and closing points of the valves are not marked. How should I proceed to mark the rim of the wheel? I know the valve timing.

The first step is to obtain the dead centres, upper and lower. This may be done by the piston, but if the motor be an old one and the timing gears worn, the method will not be as accu-

rate as utilizing the crank throws. The latter should be vertical, and by placing the piston of the No. 1 cylinder (that nearest the radiator) at the top dead centre or the completion of the intake stroke, the upper dead centre point is located. Allowance should be made, however, for lost motion in the gears or bearings as above referred to.

Having located the top or upper dead centre it should be marked, and the flywheel given a half-turn to determine the lower or bottom dead centre. This should be carefully checked before marking the flywheel.

Having marked the centres, the flywheel is laid off. In the factory the events are first laid out at the proper angular distance on a circle equal in diameter to the flywheel of the motor, and the distances from the centre markings

goes past the upper dead centre, and that the piston has begun its downward movement or intake stroke. The intake valve closes 26 degrees after bottom dead centre and the piston has started upward on the compression stroke. The exhaust valve begins to open 46 degrees before lower dead centre or before the firing stroke is completed. It remains open during and until the upper dead centre mark is passed by five degrees.

The diagram shows the points to be marked on the flywheel, and if the strokes are taken into consideration and the fact that two complete revolutions of the crankshaft, equalling 720 degrees, are necessary to obtain a power impulse for each cylinder, the work of timing will be simplified. The opening points referred to mean when the valve begins to lift. It is very probable that the valve tappet mechanism will have

Fig. 3—Illustrating Valve Timing Diagram for Marking Opening and Closing Points on Periphery of Flywheel.

measured linearly on the perimeter of the circle are then determined. These linear distances are utilized in the actual laying off of the flywheel, a steel tape scale generally being employed in the work.

Degrees or inches may be used in laying off the flywheel. Given the diameter of the flywheel it is a simple matter to learn its circumference. The diagram at Fig. 3 shows the method of marking the flywheel. In this instance the timing is as follows: Intake valve opens eight degrees after top dead centre and closes 26 degrees after lower dead centre. The exhaust valve opens 46 degrees before lower dead centre and closes five degrees after top dead centre.

The four strokes and approximate positions of the pistons are shown in the diagram, and it will be seen that the flywheel is turned eight de-

grees past the upper dead centre, and that the piston has begun its downward movement or intake stroke. The intake valve closes 26 degrees after bottom dead centre and the piston has started upward on the compression stroke. The exhaust valve begins to open 46 degrees before lower dead centre or before the firing stroke is completed. It remains open during and until the upper dead centre mark is passed by five degrees.

GERBER BECOMES PRESIDENT.

Factory of Abbott Motor Company Also Being Enlarged for Increased Output.

At the recent annual meeting of the Abbott Motor Company, Detroit, maker of the Abbott-Detroit car, the control of which was purchased last November by E. F. Gerber of Pittsburg, Penn., Mr. Gerber was elected president. The other officers are: Vice president, M. J. Hammer; secretary and treasurer, Francis B. Fick. The factory is being enlarged in order to take care of the increased output planned.

REEVES REPLACES MILES AS MANAGER.

ALFRED REEVES, vice president and general manager of Hartford Suspension Company, Jersey City, N. J., has disposed of his hold-

Samuel A. Miles, Retiring General Manager, National Automobile Chamber of Commerce.

ings in that concern, to become general manager of the National Automobile Chamber of Commerce, succeeding Samuel A. Miles, who has held the position from the very inception of the automobile industry. It is understood, however, that the latter has not been entirely eliminated by the change, but will continue to exercise a

wide influence in the management of the New York and Chicago shows, now held under the auspices of this association.

Alfred Reeves was born in Brooklyn, N. Y., Sept. 16, 1875, and became identified with the automobile industry in 1899. He was one of the early members of the New York Motor Club, and for a number of years was a writer on automobile topics for the Evening Mail, American and Globe in New York City. He helped organize the American Motor Car Manufacturers' Association in February, 1905, and was made general manager during the days when the members of that organization were resisting the so-called Selden patent litigation. When that action was finally decided and the association passed out of existence, he became general manager of the Association of Licensed Automobile Manufacturers, the rival organization, which very soon became the Automobile Board of Trade.

Some time previous to the amalgamation of the last named body with the National Association of Automobile Manufacturers, under the name of the Automobile Chamber of Commerce, Mr. Reeves resigned and identified himself with the Hartford Suspension Company.

Samuel A. Miles was born in Bristol, England, May 10, 1862. He acquired his first car in 1900, and about the same time became actively interested in the Chicago Automobile Club. Shortly after the first show was held in New York City he became convinced that something of this nature would appeal to the residents of the Middle West, and enlisted the co-operation of the Chicago Automobile Club in holding the first Chicago show. When the National Association of Automobile Manufacturers was first formed in that year, he was selected as general manager. That association was reorganized and incorporated in 1904, and Mr. Miles continued as its general manager, until its amalgamation with the Automobile Board of Trade, and has held the same position with the Automobile Chamber of Commerce, now the National Automobile Chamber of Commerce, ever since. It is stated that he retires at this time to devote his entire time to the management of the two shows above mentioned and to certain private interests.

The chamber has adopted a definite policy with respect to legislation, directing its officials to discourage by all proper means the enactment of any legislation which falls within the following classes:

Bills which impose local license or registration fees or local regulations upon automobiles or their owners, or which give authority to minor jurisdictions to regulate the operation of automobiles; such license or registration fees and regulations being in addition to those imposed or fixed by state laws.

Discriminatory bills which impose burdens upon automobiles not borne correspondingly by horse drawn vehicles.

Bills the effect of which is to impose double taxation on automobiles through the imposition of a personal property tax in addition to the exaction of registration and license fees, or otherwise.

All acts imposing an occupation tax on either agents or manufacturers of automobiles, or restricting or regulating the industry or the trade by special legislation.

All legislation requiring the use of specific or proprietary devices or attachments on automobiles in addition to manufacturers' standard equipment.

Alfred Reeves, General Manager, National Automobile Chamber of Commerce.

INAUGURATE "SAFETY FIRST" CAMPAIGN.

Important Movement Headed by Organized Motorists in Effort to Reduce the Number of Automobile Accidents---Practical Attempt to Eliminate Reckless Driving.

ORGANIZED motorists in practically every section of the country have adopted a new slogan: "Safety First". The movement is timely

1. Keep on the sidewalk.
2. Cross the street on the crosswalk.
3. Look up and down the street before you cross.
4. Don't play in the street.
5. Don't "catch on" teams or wagons or cars, or run in the street behind them.
6. Don't jump out into the street from behind teams or automobiles.
7. Before stepping off any street conveyance, look up and down the street.
8. Remember that the street is a place of danger; the sidewalk is the place for children "on foot."

Copy of "Safety First" Card Distributed Among School Children in New Haven, Conn.

and of great importance. The small proportion of reckless drivers is endangering the lives of thousands of people daily and is harmful to the whole industry—and the great majority of law abiding motorists has been seeking for some method of effectually curing this small minority. "Safety First" cannot be expected to overcome all difficulties, but it will help materially.

Statistics oftentimes can be utilized in such manner as to prove almost any desired point. It has been very difficult to secure reliable statistics respecting highway accidents, but such figures as are obtainable have been published by those interested in an effort to demonstrate that automobile accidents are increasing rapidly.

Classification of Accidents.

The National Highways Protective Society has for several years kept a record of traffic accidents of all sorts in the states of New York and New Jersey. According to this society, these are classified as automobile, trolley and wagon, and include only pedestrians knocked down or run over, and occupants of vehicles who received their injury through the fault of some other person. Accidents due to failure of equipment of the vehicle, or to faulty condition of the highway, have not been included, the intention being to note only those accidents for which the driver of some vehicle can reasonably be held to blame.

Under the automobile accidents, as classified by this

society, are included those due to motor vehicles of all descriptions not running upon rails, and all collisions of motor vehicles with all vehicles, except in a few specific cases where the other vehicle was manifestly to blame. Under trolleys are included all electric railways, street and interurban, and all collisions of trolleys and wagons. Wagons include all animal drawn vehicles. The only trolley accidents counted are those to pedestrians, or as the result of collisions. Other injuries to passengers or employees are omitted. Children include all persons under 17 years of age.

The statement of the society further sets forth that the figures are derived from the coroner's reports every month, and that the totals are all somewhat below those of the coroners, due to the difference in classification and to the fact that the definite report of the cause of an injury often does not come to the coroner's office until after the end of the month. It is added that the only large discrepancy is in the figures for wagon fatalities, where it is held probable that the correct figures are much larger than those given in the specific instances cited, in which it is stated that the total number of persons killed in New York City during 1913 by automobiles was 302, by trolleys 108 and by wagons 132. The society feels that the correct figure for wagons should be at least 170. The records of the society show:

Fatalities in New York City.

	1910	1911	1912	1913
Automobile	112	142	221	302
Trolley	148	109	134	108
Wagon	211	172	177	170

Remainder of the State of New York.

	1911	1912	1913
Automobile	132	127	149
Trolley	67	79	79
Wagon	31	28	32

1. Safety should ever be your first consideration.
2. Remember that the other fellow may do the very thing that you do not expect him to do.
3. Every cross street and every highway intersection is a danger spot.
4. Every trolley car or other highway conveyance that is stopped, coming to a stop, or just starting, is a source of danger.
5. Slow down and stop when in doubt.
6. See to it that your brakes are always in good working order.
7. Be cautious about forcing your way through a crowd.
8. Your horn is a danger signal and its unnecessary use is unlawful.
9. Be particularly watchful of children, especially near schools.
10. Consider the feelings and bear in mind the rights of others; favorable public opinion is desirable to you as a driver.
11. Life and limb are precious. Be keen to protect both from harm.
12. Speed is unnecessary, safety is imperative.

"Safety First" Rules Prepared for Consideration by Connecticut Motorists.

State of New Jersey.

	1912	1913
Automobile	91	124
Trolley	41	28
Wagon	16	26

The following table, prepared by this society, gives the number of accidents due to specific classes of vehicles or to particular circumstances of interest:

	New York City	New State	New Jersey
Motorcycles	67	190	96
No light on wagon	10	10	3
No light on automobile	18	18	1
U. S. mail	23	3	1
Taxicab	49	14	•
Fire department	26	5	4
Ambulance	24	2	2
Police and other officials	5	2	2
Children playing in street, etc.	46	12	18
Woman driving automobile	10	14	13

*A few, but not counted.

Basing fatality rates on 1,000,000 of population for various American and foreign cities, this society gives the following figures for the year 1912:

American Cities.

	Automobile	Trolleys	Wagons
New York	47	28	38
Buffalo	49	51	10
Chicago	48	89	52
Pittsburg	52	48	43
Providence	48	35	12
St. Louis	30	64	45
San Francisco	52	61	20
Baltimore	14	35	13
Washington	71	56	20

Foreign Cities.

	Automobile	Trolleys	Wagons
London	46	5	24
Berlin	23	11	31
Paris	47	25	16
Vienna	13	2	15
Glasgow	12	15	19
Liverpool	17	4	16
Edinburgh	15	5	16
Dublin	10	10	22
Belfast	17	4	12
Leeds	19	3	11

Statement of Chicago Coroner.

In this connection, it is of interest to consider an authoritative statement by Peter M. Hoffman, coroner for Cook county, Illinois, which embraces the City of Chicago. He says:

It is clear that comparisons made as to the danger between horse vehicles and power vehicles must be estimated on efficiency, as the number of miles travelled is the only rational basis on which to figure. Accurate figures compiled from the records of Chicago and Cook county show that 1912 was the first year in which the number of automobile accidents ever surpassed horse vehicle accidents, and the mileage percentage of power vehicles as compared with horse vehicles shows that automobiles now average two-to-one safer per mileage than horse drawn vehicles.

Tables accompanying Coroner Hoffman's statement show the number of passenger and freight vehicles of all classes, licensed and unlicensed, on the streets of Chicago, Feb. 10, 1914;

their average daily mileage, and their total daily mileage, accidents and fatalities for the last four years, and the average number of accidents a day for each 5,000,000 miles travelled is as follows:

Number and Daily Mileage.

	No.	Average Mileage	Total Mileage
Horse vehicles	65,118	12	781,416
Power vehicles	37,406	42	1,571,052

Accidents in Four Years.

	Total	Daily Average	Average for 5,000,000 Miles
Horse vehicles	6,047	4.15	26.55
Power vehicles	5,784	3.96	12.60

Mr. Hoffman's record of coroner's cases or fatalities for the four years show the following:

	Street Railway	Horse Vehicle	Power Vehicle
1910	175	67	52
1911	161	75	75
1912	209	49	96
1913	165	44	136

Automobiles Less Dangerous Than Wagons.

A careful analysis of these figures will demonstrate that automobiles are by no means so dangerous as they are made to appear, but there is sufficient reason for making every effort to reduce the number of fatalities. Referring once more to the figures of the National Highways Protective Society, it is stated that the percentage of children (under 17 years of age) killed during the years of 1910, 1911, 1912 and 1913 in New York City was as follows: By automobile, 45; by trolleys, 31; by wagons, 52. In the remainder of the State of New York the percentages for 1911, 1912 and 1913 were: By automobile, 26; by trolley, 25; by wagon, 42. In New Jersey, the percentages for 1912 and 1913 were: By automobile, 36; by trolleys, 36; by wagons, 50. Obviously, these percentages are based on the total number of fatalities resulting from the respective causes, and it would seem that, contrary to the general belief, accidents to children due to automobiles were much less frequent than those due to wagons.

Perhaps, because it is realized that the children of today are the men and women of tomorrow, the "Safety First" campaign now being inaugurated is finding its greatest activity, just at present, in educating the children to the necessity for the greatest amount of caution. It is unnecessary to cite more than a few cases to illustrate this phase of the subject.

Co-Operation with Public Schools.

The New Haven Automobile Club, New Haven, Conn., has distributed more than 50,000 small cards, through the co-operation of Mr. Blood, superintendent of schools, to the school

children of that city, and has posted in a conspicuous place in each schoolroom placards bearing the same rules. The Albany Automobile Club, Albany, N. Y., has adopted a simple catechism, which is virtually being made a part of the regular course of instruction in the schools of the city, with the approval of the department of education. Similar catechisms have been prepared by other clubs throughout the country and are used in practically the same manner. Examples of these are shown herewith.

The New Haven Automobile Club, and many of the others, is not content to leave the matter with issuing cards to school children, but has prepared similar cards for distribution to every member of the club and to all motorists in the city. In addition, large placards have been posted in conspicuous places, bearing the same wording.

New methods of calling attention to the slogan, "Safety First", are being devised every day. Trolley companies are volunteering to post the rules in their cars. Moving picture houses are throwing them upon the screens. Placards are being posted in large factories. Very soon everybody will be impressed with the necessity for caution, and, perhaps, it is not too much to expect that those who have been guilty of reckless driving may become imbued with the same spirit.

However, this is but the beginning. There is something bigger and deeper behind all this agitation for "Safety First". Reckless driving endangers all users of the highways—the motorist, as well as the pedestrian and the occupant of the horse drawn vehicle. The movement is one of self-preservation, of co-operation, of general humanitarianism.

PLANS FOR SUMMER MEETING.

Society of Automobile Engineers Will Assemble at Cape May, N. J., in June.

The council of the Society of Automobile Engineers has decided upon Cape May, N. J., as the

place in which the summer meeting of the organization will be held, June 23-26. The convention headquarters will be in the new Cape May hotel, where the various sessions will be held as follows:

Tuesday, June 23, meeting of the standards committee at 2 in the afternoon. Wednesday, June 24, business and professional session at 2 in the afternoon; entertainment by sections of the society at 8 in the evening. Thursday, June 25, professional sessions at 9:30 in the morning and

1. What Should You Do Before Crossing a Street?

I should stop and look both ways, first to the left (as danger will likely be nearer from that side) and then to the right. If the street is clear for at least half a block, then I can go ahead and cross the street quickly.

2. Where Is the Proper Place for You or Any One to Cross the Street?

At a crossing, and I should never cross a street at any other point, for the reason that there is less danger at crossings than at any other point.

3. When You Are Playing in the Street, What Should You Always Keep in Mind?

That I have chosen the most dangerous place possible in which to play and that automobiles and other vehicles approach swiftly and silently and are liable to kill me if they strike me.

4. Why Should You Not Play in a Street Frequently Used by Automobiles or Other Vehicles?

Because I am apt to bewilder the drivers, thus making them lose control of their vehicles, which would be dangerous not only to me but also to others.

5. What Would You Do if You Were Standing in the Middle of the Street and Should See Automobiles or Other Vehicles Coming Both Ways?

If I am caught in the middle of the street with vehicles approaching from both directions I should stand perfectly still and let the vehicles pass around me, because they are not likely to run over me if I do not move.

6. What Danger Is There in Stealing a Ride on an Automobile or Other Vehicle?

I am in danger of falling off and being injured, or I may be run over by another vehicle when I jump off. This is a very dangerous practise and I should avoid it.

7. In Case a Child or Any One Is Injured by an Automobile, What Is the First Thing to Do?

I should secure assistance and get the injured one to the nearest hospital as quickly as possible.

8. Should You Ever Throw a Stone at an Automobile or Other Vehicle and Why?

I should never throw a stone or other missile at any vehicle because I might hurt some one or damage the vehicle, or cause the driver to lose control, which might result in an accident and for the reason that it is against the law.

9. Should You Look After Younger Children in Crossing Streets, and Why?

I should assist younger children in crossing the street because they cannot think as quickly as I can and may not realize the danger which threatens them.

10. What Should You Do if You See an Automobile or Other Vehicle Unattended Standing on the Street?

I should not go near it.

11. Should You Ever Use Roller Skates, Coasters or Other Similar Contrivances on the Streets?

Never, because they are always dangerous, particularly on the streets frequented by automobiles and other vehicles, for the reason that I cannot perfectly control my movement and, therefore, am continually liable to be severely injured or killed.

Example of Catechism Now Being Taught in Public Schools of Many Cities—This One Was Prepared in Co-Operation with the Board of Education in Albany, N. Y.

2 in the afternoon; dinner and European trip lecture at 8 in the evening. Friday, June 26, professional session at 9:30 in the morning, with final adjournment about 1 in the afternoon.

It is expected that some 600 members and guests will be in attendance.

Truffault-Hartford shock absorbers were fitted to Edward Pullen's Mercer, with which he won Grand Prize, Santa Monica, Cal., Feb. 28.

MACHINERY, TOOLS, EQUIPMENT AND SUPPLIES.

MANY proprietors of garages complain that it is impossible to prevent a shrinkage in handling gasoline, as more or less of the fuel is used in the repair shop, etc., and it is difficult to check up the amount utilized. The Charles H. Simerson Company, 4135 Hudson boulevard, West Hoboken, N. J., has been organized to manufacture the Pumplok, which is held to solve the waste problem and to possess other practical features.

Simerson Pumplok.

One of the qualities of the device is that it is stated it may be attached to a standard pump in 10 minutes by engaging the main shaft by means of a slotted shaft, the construction being retained in place by an adjustable clamp that is locked and sealed, as shown in an accompanying illustration. It not only prevents unauthorized drawing of gasoline, but checks the amount drawn by each person having access to the pump.

The drawing of fuel is made possible by the use of key checks, each person being supplied with a given number bearing his number or individual design. Consequently, each must account for as much gasoline as represented by the checks found in the Pumplok's receptacle. A simple tally sheet is utilized and the operator sets down the quantity drawn, and the price for cash or charge sales.

A separate counter is incorporated, showing tenths of a gallon, which may be adapted to single or double acting pumps and to indicate the actual amount of gasoline drawn, whether in even gallons or fractions. A separate key check is required for each gallon or fraction thereof, and the pump is locked at the completion of each drawing, so that the next operator cannot take advantage of the fact that only a fractional quantity was drawn by the previous workman. The amount drawn is set down on the tally sheet as shown by the counter.

If any extra checks appear the attendant whose number they bear can be called to account. This prevents charge sales or even cash sales from being forgotten. It is stated by the inventor that it is impossible to remove the pump

gear housing with its gears, and draw fuel by actuating the rack in other than the usual manner.

AUTO-FLEX TUBING.

The National Metal Molding Company, Pittsburg, Penn., is manufacturing a new flexible tubing termed Auto-Flex. It is designed especially for enclosing wires utilized in electric lighting on motor cars, and fittings are also supplied. It is made in two forms, type A being made up of selected rigid fibre cord coiled upon itself in the form of a helix and tightly interwoven with very tough thread to form a tube, which is treated with a moisture proof compound. A covering of yarn is woven over the tube.

Type B is constructed in a similar manner, with the exception that the outer covering is braided and the mica finish is not used. It is utilized for wiring to the headlights or to any other point where the tube is exposed, and its surface is smooth for painting. Type A is employed for concealed work, such as under the hood or upon the chassis.

The fittings have been standardized, and particular attention has been paid to centralizing control and the distribution of the lighting circuits in one box and to the separation and arrangement of contact strips, so that connecting and testing is simplified.

STEINMETZ MUFFLER.

Joseph A. Steinmetz of the Janney, Steinmetz Company, Philadelphia, has been granted a patent for a muffler for internal combustion engines which is held to be very efficient in reducing noise and back pressure. The design, which is shown in section in an accompanying illustration, includes the usual outer casing, which is

Steinmetz Muffler, a Light Weight, Compact Design.

constructed of very light thin metal.

A small concentric tube passes axially through the larger member, and is provided with

perforations, and partitions are included as indicated. Loosely mounted on the inner and fitting the outer tube, are oppositely turned perforated resilient rounded cups. These cups

Hoyt Ford Magnetometer.

are so arranged that one receives the gases from the perforations and the other discharges. The passage of the gases is easily traced and it will be noted that they pass out into the open air through slots.

Features of muffler emphasized are: Light weight, easily disassembled and assembled for cleaning, etc.; efficient radiation of heat and the elimination of back pressure.

K & B ADJUSTABLE WRENCH.

The Kilborn & Bishop Company, New Haven, Conn., is manufacturing the K & B adjustable wrench, which opens on an angle of 22.5 degrees with the handle, permitting of its use in places difficult of access with ordinary tools. All parts are interchangeable and carefully fitted. The movable jaw and handle are each a solid piece steel drop forging. The shape of the handle is such that the hand readily becomes conformed to it.

HOYT FORD MAGNETOMETER.

The Hoyt Electrical Instrument Works, Penacook, N. H., maker of fine electrical indicating devices, has brought out a new magnetometer for the model T Ford which presents many practical features and is moderately priced. The Hoyt differs from other instruments utilized to ascertain the condition of the Ford flywheel magneto in that it is connected permanently in the circuit, being mounted on the dash. It is a sturdy little instrument, and is but two inches in diameter.

As will be noted by the accompanying illustration, the dial is calibrated, the letters indicating Poor, Medium, Good and Excellent. With the magneto operating, the indicating hand moves over the dial, indicating the condition of the generator at various speeds. The efficiency of the magneto is determined easily. After installing the magnetometer, readings at various speeds are taken, and by comparing these with those taken later, it is a simple matter to learn if

the efficiency of magneto is not up to standard.

The Hoyt instrument is easily attached by drilling two .1875-inch holes in the dash and securing the studs by lock washers and nuts. The wiring is simple and the entire construction can be installed in a few minutes. The Hoyt is constructed with the same care and high grade material for which the product of this concern is noted. Each instrument is carefully tested.

NEW BATTERY CATALOGUE.

The Electric Storage Battery Company, Philadelphia, is issuing a new catalogue, SL, describing the Exide battery utilized with automobile lighting and starting systems. It contains very complete information and data on the subject of batteries and will be forwarded on request.

NEW SIZES IN DAYTON TIRES.

The Dayton Rubber Manufacturing Company, Dayton, O., maker of the Dayton airless tire, announces that it is ready to supply its product in 28 by three and 30 by three-inch sizes for cyclecar service.

BASTIAN GARAGE OUTFIT.

The General Utility Company, 1326 Ogden street, Philadelphia, is marketing a line of air compressors for garages and service stations. These include belt and gear driven pumps and equipments with and without tanks. That shown in an accompanying illustration is the model E, an electrically operated outfit, which is without a tank and is held to be very efficient and economical of current.

The outfit, which includes pump, electric motor, gauge, safety valve, 20 feet of hose, indicating starting switch, 20 feet of cable and plug, is mounted on an oak platform 22 by 24 inches. The equipment is moved easily about the garage, as it is mounted on rollers, suitable handles being provided. The General Utility Company will forward catalogue giving details and trade prices on request.

Bastian Model E Garage Outfit.

IMPROVED ROADS AND MOTORING LAWS.

California Supreme Court Decides New Law Is Constitutional---Committee Named to Watch Legislation in Bay State---New York Seeks to Increase Registration Fees.

THE supreme court of California has decided that the law enacted by the legislature of 1913 is constitutional. Several points were raised by organized motorists, although the principal objection was to the registration fee based on the horsepower rating, ranging from \$5 to \$30. In the opinion, which was written by Judge Henry Melvin, the court says:

Repair of the public highways is not a police measure, yet it is evident that the bill was passed for the principal purpose of raising revenue for use in the upkeep of such highways. The court is not concerned with what use is to be made by the state with the revenue derived by the tax, and the rest of the act would be valid, even if that clause relating to the distribution of the funds were void.

The act is not local or special in its nature because a greater portion of the funds is to be expended outside the cities. The state is charging for the privilege of using the roads for these highly destructive vehicles at a rate of speed not attainable by those propelled by animal power. The privilege is open alike to the rural and urban owner of a motor car.

In the statute we are endeavoring to construe there is an attempt to apportion the charge with some reference to the destruction or wearing power of each motor vehicle. While we cannot say that the relative horsepower of vehicles is the most scientific basis of measuring their potency of injury to the roads, we cannot say that it is not without justification.

MANY MASSACHUSETTS BILLS.

Motoring Organizations Appoint Committee to Have Charge of Legislative Matters.

A committee representing the Bay State Automobile Association, Electric Motor Car Club, Massachusetts State Automobile Association, Massachusetts Automobile Operators' Association, New England Section of the Electric Vehicle Association of America, Boston Automobile Dealers' Association and the Boston Commercial Motor Vehicle Association, has been appointed in Boston to consider bills pending before the present session of the legislature. It would appear, from the list of such bills made public, that this committee would be exceedingly busy.

The provisions of these include the following: Increasing the registration fees on trucks to \$5 a ton; raising the renewal fee for operators from 50 cents to \$1; fixing a maximum speed limit of 25 miles an hour; compelling horse drawn vehicles to carry lights in all sections of the state; eliminating the provision in the present law admitting non-residents for a period of 10 days only in any calendar year; increasing the penalties for

reckless driving; providing a maximum sentence of five years for taking cars without permission; fitting mudguards to prevent splashing behind or sideways more than two feet; displaying two side lights, one of deep green color on the right and one of deep red color on the left, the glass to be of magnifying power, not ordinary common glass, etc.

NEW LAW IS PASSED.

Understood That Ohio Motorists Will Not Object to Registration Fees.

The business for which the special session of the Ohio legislature was called having been completed by the passage of a new motoring law, to take the place of the so-called Warnes law, held by the courts to be unconstitutional, that body has adjourned sine die. The new measure provides for registering all motor vehicles on a flat rate basis—electrics at \$3, gasoline and steam machines at \$5, and cars with manufacturers and dealers, \$2 each.

The sections of the Warnes bill, providing for the examination and registration of chauffeurs, were re-enacted. By a two-thirds vote the law was made effective immediately, instead of waiting 90 days as usual. It is understood that the motoring organizations will file no objections to the flat rate fees, which are practically the same as those in force under the old law.

UTAH AIDS COLORADO.

Pikes Peak Ocean-to-Ocean Highway Will Be Continued Through Former State.

As a result of a conference between officials of the Salt Lake City Commercial Club and the Pikes Peak Ocean-to-Ocean Highway Association, the latter being composed of people representing several counties in Colorado, Feb. 24, it was formally decided to adopt measures looking toward an extension of the highway, now under process of construction across Colorado, to Salt Lake City, by way of Jensen, Vernal, Roosevelt, Colton and Provo. The meeting was held in Provo, and was attended by county commissioners and representatives from various Utah coun-

ties interested. In consideration of this promised co-operation the Colorado committee pledged that the work necessary between Meeker and the Utah line would be completed by July 1.

By this action it is definitely decided that the Pikes Peak Ocean-to-Ocean highway will meet the Lincoln highway at Salt Lake City. The Utah people have pledged that they will take up the work with county officials in Nevada and California and bring about the early organization of units in those states. The Colorado committee will now turn its attention toward the extension of the route eastward through Kansas, Missouri, Illinois, Indiana and Ohio.

It is not the purpose of the Colorado organization to detract in any way from the importance of the Lincoln highway movement, but rather to afford an alternate transcontinental route over what has been known as the Midland trail. The work in Colorado has been under way for some few years and much of the highway across that state has been placed in first class condition. Already some \$200,000 has been expended, and work contemplating the expenditure of between \$100,000 and \$200,000 is planned for 1914.

INCREASES REGISTRATION FEES.

New York Legislature to Consider National Highways Protective Society's Bill.

A bill prepared by a committee representing the National Highways Protective Society, New York City, headed by President Frederic R. Coudert, has been introduced in the New York legislature by Senator Walter R. Herrick. In effect, it would amend the so-called Callan law by increasing the registration fees for motor vehicles and reducing the driver's license fee from \$5 to \$3. It is expected that the bill will produce at least \$500,000 annually for highways.

Under its terms machines are divided into classes, according to horsepower and weight, with fees ranging from 50 cents to \$1 a horsepower, according to class. Commercial vehicles weighing over two tons are required to pay an additional fee of \$10. Electric machines, except trucks of more than two tons weight, pay a flat rate of \$10 for registration, irrespective of horsepower. The registration fee is to be the only tax on motor vehicles, except in the case of machines in the hands of manufacturers and dealers, and those that may be used for "hacking" purposes.

Local ordinances regulating automobile traffic as differing from other traffic are prohibited,

except in cities of the first class. Speed limits are set for other cities, towns and villages. Drivers must not approach within eight feet of a street car which has stopped, and must bring their machines to a dead stop upon signal from any person driving a horse. Motorcycles are required to carry number plates.

THE LINCOLN HIGHWAY.

City Officials Take Action Renaming Sections Traversing Their Municipalities.

The hearty co-operation of city officials along the route of the Lincoln highway, from New York to San Francisco, is being demonstrated in a practical manner by the recent action of several city councils, in changing the names of streets traversed by this thoroughfare. As is more or less well known, the Lincoln Highway Association, with headquarters in Detroit, is behind a movement to construct a concrete roadway across the continent, and a fund of \$10,000,000 is now being raised for this purpose. The route has been selected, and much of the fund has been subscribed.

Following the example set by other cities, the Automobile Club of Aurora, Ill., has prepared a petition to be presented to the city council, requesting that the name of the street traversed in that city be changed to Lincoln way. In South Bend, Ind., B. C. Walters, Rome C. Stevenson and M. L. Williams have been appointed as a committee to draft an ordinance changing the name of Vistula and Michigan avenues to Lincoln way. In Kearney, Neb., the principal street will be called by this new name, and in many points in Pennsylvania, Indiana, Iowa, Wyoming and other states, the same programme is being carried out.

Among the latest city councils to take such action are those of Lisbon and Nevada, O. In the former city the name of Walnut street has been dropped, and in the latter, North Morrison, Balliet, Main and Center streets have been designated as Lincoln way.

Citizens of Chambersburg, Penn., recently erected an arch at the square in the centre of the city calling the attention of travellers to the fact that it was over this route that Gen. Robert E. Lee marched the Rebel army to Gettysburg. Beneath this arch there now hangs a sign reading: "Now the Lincoln Way". The pillars on either side bear the official marker of the association—a strip of red above and a band of blue below a white background bearing the words "Lincoln Highway" and the letter L.

CYCLECARS REVEALED AT BOSTON SHOW.

Largest Number of Makes Yet Displayed at One Time in America--New England Manufacturers Well Represented in the List--Some Entirely New Models.

EXCEEDING in number of makes those presented at any previous display in this country, the cyclecar section of the Boston automobile show was in many respects one of the most important features of the exhibition. All told, there were 14 different makes of machines, as follows: Bantam, Dudley, Duryea, Economycar, Euclid, Herreshoff, Imp, Laconia, LaVigne, Mercury, Merz, Salvador, Trumbull and Twombly. The Duryea, Herreshoff and Salvador were late in arriving, and it was not until Wednesday that the list was complete. Each maker was represented by at least one model, the Euclid and Mercury by two and the Bantam by a complete car and stripped chassis.

Four of these were seen at New York—Imp, LaVigne, Trumbull and Twombly—while the

land is something of a cyclecar producing centre itself. The Bantam and Salvador are manufactured in Boston; the Trumbull in Bridgeport, Conn.; the Euclid in New Haven (or West Haven), Conn.; the Laconia in Laconia, N. H., and it is stated that the Economycar, while heretofore produced in Indianapolis, is soon to be transferred to Boston.

Strictly speaking, while all the makes shown at Boston are listed as cyclecars, they must be classified, under the definitions of the Cyclecar Manufacturers National Association, as true cyclecars and light cars. The Euclid, LaVigne, Salvador, Trumbull and Twombly come under the latter classification. Most of these machines have been described at some length in these columns, and the details should be somewhat familiar to readers of The Automobile Journal.

Bantam a True Cyclecar.

The Bantam is entirely new. It is manufactured by the Bantam Motor Company, Boston, and the car and chassis on view were produced in the shops of the Lenox Motor Car Company of that city, although it is stated that that concern has no connection with the maker. The car has wheelbase of 86 inches, tread of 46, and weighs about 700 pounds. The two passengers are seated side by side.

The motor is a two-cylinder, air-cooled V unit, with 3.5-inch bore and 3.75-inch stroke, rated at 9-14 horsepower. Power is transmitted by friction discs and chain to a semi-floating rear axle with differential. The wire wheels carry 28 by three-inch tires. The driver is located at the left, with control levers in the centre, and entrance to the body is by one door at the right. At the rear is a compartment for luggage, which also provides room for a set of dry cells supplying current for electric lights front and rear.

Duryea's Roller Drive.

While it has been known for some that Charles E. Duryea, who produced his first gasoline car in 1891, was working on a cyclecar, the complete details were not made public previous

Where the Laconia Was Displayed at Boston Show—Dudley in Background.

Zip also was exhibited during the closing days of that display. At Chicago this branch of the industry was represented by the Imp, Mercury, Coey Junior, Keller-Kar, Trumbull, LaVigne and Rex. At Detroit, which is reggraded as the centre of the cyclecar, as well as the automobile industry, there were displayed the LaVigne, Rocket, Packet, Mercury, Cricket, Hawk and Detroit.

New England Well Represented.

It will be seen that the Boston show has set an entirely new record in this field, and because of the number of makes on display and the splendid public interest in cyclecars generally, it readily will be appreciated that this was an important feature of the exhibition. Moreover, it was pretty thoroughly demonstrated that New Eng-

to the opening of the Boston show. The Duryea, which is a true cyclecar, is made by the Cresson-Morris Company, Philadelphia, and departs from what might be termed standard practise, in that the motor is located at the rear. The hood at the front, which causes the car to have a conventional appearance, is with a detachable door and provides excellent carrying space for luggage, etc. Two persons are seated side by side. The wheelbase is 100 inches and the tread 44. The weight is about 600 pounds.

The machine was shown equipped with a De Luxe motor, but it is understood that a two-cylinder, four-cycle, air-cooled, opposed engine, rated at 12-15 horsepower, will be employed. Power is transmitted by the Duryea patented roller transmission, which provides three forward speeds and reverse. The shaft carrying these rollers at either end really is an extension of the crankshaft, and it will be understood that the rollers always travel in the same direction. A ring on the inner side of the wheel rim engages with a slot on the roller, three slots providing the three speeds, and when the lowest speed groove is made to contact with a ring midway of the spokes, the reverse is engaged. When the rollers are brought out of contact with both rings, a neutralizing effect is obtained. It thus will be seen that the power plant and transmission are virtually a unit, and the whole of this mechanism is placed almost directly over the rear axle.

The fuel tank is located under the hood at the rear, just behind the seat. The wire wheels are fitted with 28 by 2.75-inch tires in front and 28 by three-inch rear. The equipment includes lamps, horn and tools, and a top and windshield are listed as extras.

Worm Driven Laconia.

Another entirely new model is the Laconia, made by H. H. Buffum in the shops of the Laconia Car Company, Laconia, N. H., which concern is well known as maker of trolley cars. It is stated that it is the intention of Mr. Buffum to produce only 100 cars the first season. The model shown is said to have been on the road since last June, and to have demonstrated its practicability in every way, but it is not desired to engage in quantity production until such time as the public has had opportunity to test the design and construction in actual service.

The car has wheelbase of 90 inches and tread

of 40. The weight is about 400 pounds. The two passengers are seated, one a trifle behind the other. As shown, the motor is a twin-cylinder, seven horsepower Indian, although it is understood that an engine of original design will be employed later. This drives by shaft to a friction disc, located directly over the rear axle, the friction wheel transmitting energy to a worm assembly. The spring suspension is double cantilever. The driver is located at the left, with central control levers. The equipment will include a top and windshield, etc.

Salvador Light Car.

The Salvador light car is made by the Salvador Motor Company, 126 Massachusetts avenue, Boston, with factory at 28 Scotia street. The designer is G. B. Mansur of Boston, who is said to have been identified with the automobile industry for the past 12 years, with companies in this country and abroad. The car seats two passengers side by side, and has wheelbase of 100

Duryea Model, of Conventional Appearance, but with Motor at the Rear.

inches and tread of 40. The weight is not stated.

The motor is a four-cylinder, water-cooled, L head unit, cast en bloc, with bore of 70 mm and stroke of 100 mm (about 2.75 by 3.9 inches). Lubrication is by constant level splash with pump circulation, and cooling by thermo-syphon. The clutch is a cone, and the transmission affords three forward speeds and reverse. The wheels are of wire and carry 28 by three-inch tires. The driver is located at the left, with central control levers.

Twombly with Poppet Valve Motor.

In the main, the other machines shown have not been changed materially from the designs originally announced, although there has been slight modification of the body lines with a few. The Twombly model is now fitted with a four-cylinder poppet valve motor, this being produced by the Driggs-Seabury Ordnance Corporation, Sharon, Penn. It is announced, however, that the Twombly Car Corporation, New York City,

has not abandoned its intention of using the special Twombly piston valve motor, and that experiments with this product are still under way at the factory of the company in Avondale, N. J.

During the week several rumors of the formation of additional cyclecar companies in Boston and elsewhere in New England were heard, but nothing definite was learned. It is known, however, that several men are interested in the subject, and it is not unlikely that public announcements will be forthcoming within a few weeks or months. There can be little doubt of the fact that the excellent display made by this branch of the industry in connection with the Boston show will have the effect of still further increasing the interest of New England people in cyclecar productions.

CYCLECAR CLUB FORMED.

New England Enthusiasts Organize During the Progress of Boston Show.

One of the interesting events in connection with the annual Boston automobile show was the organization of the Cyclecar Club of New England, which was consummated in the Hotel Oxford, Wednesday evening, March 11. The meeting was called to order by Dr. Charles G. Percival, who has been identified with the sale of the Imp; and among those present were Vice President R. F. Kelsey and Secretary F. E. Spooner of the National Cyclecar Club of America, both of whom spoke respecting the urgent need of an organization of this character in New England.

It is understood that permanent quarters will be located in the Hotel Oxford, and the club starts with a membership of 21, representing those interested in 18 makes of cyclecars. The officers are as follows: President, E. P. Blake; first vice president, H. Ross Maddocks; second vice president, C. J. Fischer; secretary, C. S. Roberts; directors, F. J. Tyler, J. S. Richards, F. S. Corlew, A. C. Gosse and Joseph E. Green.

AND THE PRIDEMORE, ALSO.

Designed by W. A. Pridemore and Sold by F. W. Skinner in Northfield, Minn.

One of the latest cyclecar models is the Pridemore, designed by W. A. Pridemore and produced by the Pridemore Machine Works, Northfield, Minn. F. W. Skinner has charge of the sales end of the business. Three body types are

to be fitted, a tandem two-seater, side-by-side roadster, and delivery wagon. The wheelbase is 100 inches and the tread 40. The chassis weighs about 450 pounds and the completed car about 600.

The motor is a two-cylinder, air-cooled unit, rated by the maker at 12-14 horsepower. Power is transmitted by friction discs and thence by chains to the rear wheels, with a differential incorporated in the jackshaft. The wire wheels carry 28 by 2.5-inch tires.

EXPECTS CAR SHORTAGE.

Krit Dealer Makes Analysis of Situation at Conclusion of Western Trip.

That there is to be a shortage of motor cars of moderate price during the 1914 season is the prediction of F. W. Pilling, western sales manager of the Krit Motor Car Company, Detroit, upon his return to the factory after a five weeks' trip throughout the Middle West. Mr. Pilling finds a strong demand in that section for cars in the \$1000 class, and he attributes this to the general condition of prosperity that prevails in the districts visited by him.

In making his analysis of the situation, he says that dealers are ordering in car load lots, and that his concern is sending double deck shipments every week to such points as Minneapolis, Kansas City, Chicago, St. Joseph, Des Moines and Omaha.

MILLER, SECOND AND THIRD.

This Make of Tires Fitted to Marmon and Alco Machines Finishing at Santa Monica.

As stated in the last issue of The Automobile Journal, Miller tires, made by the Miller Rubber Company, Akron, O., were fitted to the Touraine car, driven by Joermans to fourth place in the Vanderbilt Cup race at Santa Monica, Cal. The same make of tires also was fitted to Ball's Marmon and Taylor's Alco in the Grand Prize. These machines finished in second and third place.

It is of interest, in this connection, to note that Miller tires were used by Teddy Tetzlaff on his Fiat with which he secured a world's road racing record over the same course in 1912. The Miller company asserts that none of these shoes was specially made in any way, and that anyone may select a tire of identically the same material and workmanship as those used in these races, from any Miller dealer.

HINTS FOR NEW CAR OWNERS.

Care and Maintenance of Simms Magnetos—Ford Flywheel Magneto Hints—Adjusting Bearings and Removing Wheels of Premier Rear Axle.

AS SIMMS magnetos are standard equipment on several 1914 models, a knowledge of the operation of their components will be of

Fig. 1—Circuit Breaker of Simms Dual System.

value in their care and attention. The product of the Simms Magneto Company, East Orange, N. J., comprises two forms, the independent or true high-tension instruments, known

as types SU4, SU6, SUW4 and SUW6, and dual forms listed as types SU4S, SU6S, SUW4S and SUW6S. The last named are exactly the same in general construction as the independent types, with the exception that the contact breaker is equipped with two conductor brushes and a commutator is used in place of the usual dust cover on the breaker box. The figures utilized designate the number of segments employed with each magneto; that is, the 4 represents an instrument adapted for service with a four-cylinder motor and the 6 a six-cylinder.

True High-Tension Types.

The Simms magnetos employ a double wound armature; that is, the primary current generated is induced in a secondary winding in the instrument itself and no coil is utilized to transform the low-tension current.

There is but little for the owner to do other than cleaning, oiling and maintaining the proper gap of the contact points and spark plugs. The circuit breaker mechanism of the dual type instrument is shown at Fig. 1. It is identical with that employed with the independent type, with the exception that the brushes are not used with the latter construction.

Proper Break of Points.

It is important that the gap of the contact points conform to the gauge provided with each magneto, and that that of the spark plugs be 1-50 inch, about the thickness of an ordinary 10-cent piece. The method of adjusting the points is sim-

ple. The armature is rotated by slowly turning the starting crank until the fibre block makes contact with the cam ring at its thickest portion. At this point the contact members should be fully separated. If the gauge slips in easily between the points it shows that the break is too large. By loosening the locking nut on the fixed platinum pointed screw, the latter may be screwed outward or brought closer to the movable point on the interrupter lever. The adjustment should be so made that the gauge will fit snugly. It is important that the lock nut be tightened upon the completion of the work. The steps were illustrated in the Feb. 25 issue of The Automobile Journal. The wiring plan of the independent type is shown at Fig. 3 A. Its simplicity is apparent.

Simms Dual System.

The Simms dual system differs from conventional practise in that the dash switch contains no induction coil or high-tension switch, and has but three low-tension connections to the switch and one to the battery, as will be noted by the plan presented at Fig. 3 B. There are but two contacts in the switch, "On" and "Off", and these are not sliding. One of the qualities of the design emphasized is that any error made in connecting the magneto to the switch will not injure the system, and the battery cannot be exhausted if the switch be left at the "On" position with the motor inoperative.

A vibrating or battery spark is produced through the dual coil, which is of the cartridge type and water proof. Its interior consists of a magnet wound with heavy wire, a condenser and a rapid vibrator. The sec-

Fig. 2—Commutator of Simms Dual System.

ondary winding of the magneto's armature is utilized to transform the battery current, and when the battery contact but-

ton on the switch is locked in place, and the conductor brushes (Fig. 1) are on the live (short) segments of the commutator shown at Fig. 2, a constant shower of sparks is delivered to the cylinder on compression.

Function of Commutator.

The commutator referred to consists of a disc of heat resisting, insulated material, into which are molded four bronze segments with the four-cylinder unit and six with the six-cylinder magneto. Two of these segments are connected with the outside terminals of the commutator, the others serving simply as a path for the contact breaker brushes. The commutator replaces the usual end cover; is held in place by a flat spring, and is retained in its proper position by a substantial pin projecting from the timing lever, which engages a corresponding keyway or slot in the commutator. The last named is displaced by pushing the flat spring to one side.

the lower or + terminal on the commutator, and that the other lead from the battery runs to the switch. The ground is from the switch. The remaining leads from the switch are connected to the commutator as indicated.

The Simms Magneto Company recommends the use of a drop or two of 3-in-1 lubricant every 1000 miles of service. The two oiling holes are marked.

Before condemning the action of the magneto it is important that all wiring and connections be examined. With the independent type it is necessary that the wire leading from the breaker box cover be not grounded except when the switch is moved to the "Off" position. If the lead be suspected of fault, it may be tested by removing it from the cover and noting the operation of the instrument. If the spark jumps the safety spark gap it is probably due to a loose connection, broken cable, dirt on the conductor or brass bar

Fig. 3—Wiring Diagrams of Simms Magnets: A, Independent Type; B, Dual System—Note the Small Number of Leads with the Latter.

The vibrator will require attention only after long periods of service, due to its design and the use of very large contact points. To adjust the vibrator contact points it is not necessary to disassemble the switch, a screw for this purpose being provided in the centre of the push button. By inserting a pin, supplied with the switch, the cover plate may be turned one-quarter of a revolution and removed, exposing the mechanism. By slipping the spring locking ring out of place, the entire mechanism may be displaced, if desired. The only adjustment is to bring the contact points closer together, by the screw member as previously explained.

Wiring Plans.

The wiring plan of the dual system employed with a four-cylinder motor is shown at Fig. 3 B. It will be noted that the positive + terminal of the battery, a six-volt member, is connected to

under the magnets on the open type, or oil or dirt on contact points. The latter should be kept clean and no part of the circuit breaker mechanism lubricated, as oil will create troubles.

PREMIER REAR AXLE.

The Premier Motor Manufacturing Company, Indianapolis, Ind., gives the owner some good advice in its instruction book for the series X Premier machines. The company warns the motorist against attempting to improve the adjustment of the differential and drive pinion bearings, stating that the work was performed properly at the factory. Means are provided, however, for the purpose of taking up the wear and for disassembling and assembling. A knowledge of the rear axle will be of value to the owner in the event of an accident, etc.

A sectional view of the axle is shown at Fig. 4, with the components lettered. Three adjustments are provided—for eliminating end play of the drive pinion on its bearings; for moving the pinion, or meshing it with the bevel gear, and for moving the differential sideways.

Adjusting Differential.

The differential is accessible by removing the plates, and by using a large sized screw driver the differential clamp collar P can be manipulated. A plug W, when removed, permits of inspection of the mesh of the teeth of the pinion gear. The pinion adjusting sleeve S fits into milled slots in the sleeve, preventing its turning. All threads are standard right hand.

To adjust for a season's wear, for example: Set up the clamp collar T until all end play or thrust is eliminated from the pinion, but care must be exercised not to have the bearing too tight, else it will be ruined. Remove the plug S and, with the wrench provided for the work, screw the pinion adjusting sleeve U one 24th of a turn or one slot, which amounts to .003 inch advance of the pinion. Loosen the screw C of the clamp collar P and screw the collar away from the differential a part of a turn just enough to eliminate all of the end play, taking care that the bearings will not be subjected to undesirable stresses. Tighten all screws securely when the work of adjusting is completed. Do not loosen the clamp nut O when adjusting for wear, and allow no one except an expert to adjust for noises. The wear of the gear teeth increases the back lash, but this does no harm and causes no noise, and cannot be taken up without affecting the quietness of the gears.

Meshing Gears.

In adjusting the gears for noise the object desired is to set the gears relative to each other, both longitudinally and laterally, so that the pitch surfaces are exactly tangent, when the teeth will slide on and off each other without perceptible knock or jar. The pitch surfaces are imaginary surfaces, and their relation can only be guessed at by the sound of the teeth running together. As the teeth wear the back lash is of course, increased, but the imaginary pitch surface is unaffected, so it is evident that in adjusting for noise any notice of the back lash will only be misleading.

To remove the rear axle, jack up and place steadying supports under the frame just in front of the axle. Raise the frame until the wheels just clear the ground, then jack up the axle until the jacks carry its weight. Next remove the wire E and screws F from the spring seats and the bolts Y from the rear universal joint. If the axle is lowered to the floor it can be rolled out from beneath the car, the torsion rod slipping from its hanger near the rear of the transmission.

Displacing Wheels.

To remove the rear wheels, take off the hub cap and nut K with the special wrench provided for this work, and in place of the hub cap use the wheel puller which comes with each Premier car. Raise the axle until the wheel clears the ground and screw the large set screw of the wheel puller into the last named member, pushing the axle before it. If the wheel refuses to start, tap the head

Fig. 4—Premier Rear Axle, with Components, Utilized in Adjusting, Lettered.

of the set screw with a hammer, and at the same time turn the screw.

Removing Wheels.

In replacing, the wheel is put on first and the tapered bushing I next. After making sure that the three-jawed clutch of the wheel is properly entered in the clutch of the axle shaft, tighten the nut K as snugly as possible. The nut should be secured with a good cotter pin. The nut K should also be retightened after the car has been run a short distance and the cotter pin should be replaced.

The axle shafts can be displaced after the wheels have been removed. Displace the wire H that holds the six screws G and the outside bearing cap J, and, using the axle itself as a ram, carefully jar the bearing from its seat. In replacing, be sure to rewire the screw G securely.

IN THE COMMERCIAL VEHICLE FIELD.

Plans Completed for Boston Truck Show, Only Exhibition of National Importance This Year—Motor Vehicles in Army Service—New Designs Announced.

BECAUSE of the importance of New England as an industrial centre and of the interest heretofore displayed by its business men in the mechanical transport, it is safe to predict that the third annual show of the Boston Commercial Motor Vehicle Association, which opens in Mechanics' building, Boston, the evening of March 17 for the remainder of the week, will prove a decided success from every viewpoint. As a matter of fact it will be the only exhibition of motor trucks and business wagons of national prominence this year, since the manufacturers, as represented by the National Automobile Chamber of Commerce, decided early last year to hold no display of this character either in New York or Chicago during 1914.

In effect the Boston motor truck show is a part of the annual Boston automobile show, which will close Saturday evening, March 14. The interval of practically three days is no more than sufficient to permit the removal of the large number of passenger vehicles on display this week, and arrange the commercial cars for inspection. These latter will be staged in the same setting as that which has occasioned so much favorable comment, and which is given more detailed consideration elsewhere in this issue.

Display on One Floor.

This statement needs slight modification, since the vehicles to be displayed in this second section will be found only on the first floor of the building. Thus the show will be confined to Exhibition and Grand halls, a plan which undoubtedly will meet with the entire approval of those who seek opportunity to compare the merits of the various makes and models.

Thus far it would appear that there were to be 32 different makes of machines on exhibition, but this number may be increased very materially before the doors actually open. It always has been true that there were many late comers, and there is some little evidence that this plan will be followed by several manufacturers this year. The present list practically includes only those vehicles represented by dealers in Boston, and contains 28 makes of gasoline cars, three of electric and one of steam. The management announces that it has reason to expect a total of at least 50.

As has been true of all of the automobile

shows held under the auspices of the dealers in Boston, this third annual exhibition of the Boston Commercial Motor Vehicle Association, which is composed of the dealers handling motor truck lines, will be under the direct management of Chester I. Campbell. The officials of the association are: President, J. S. Hathaway, representing White trucks; vice president, J. W. Maguire, Pierce-Arrow; secretary, Chester I. Campbell; treasurer, Day Baker, representing the G. V. electric line.

The list of exhibitors, as compiled to date, is presented below.

List of Exhibitors.

Abrams Company, Myer, 159 Vassar street, Cambridge, Mass. Lauth-Juergens one, two, three and five-ton trucks.

Alma Motor Truck Company, Alma, Mich. Two Republic one-ton wagons.

American Tire Company, 11 Suffolk street, Holyoke, Mass. Airless tires.

Autocar Company, 642 Beacon street, Boston. Autocar chassis, hotel bus and four delivery wagons.

Baker Motor Sales Company, 400 Massachusetts avenue, Cambridge, Mass. Two Selden one-ton wagons and one five-ton model.

Boyd, F. Shirley, 903 Boylston street, Boston. R. I. V. ball bearings, Multibestos brake lining, etc.

Bulck Motor Company, 15 Lawton street, Boston. Bulck chassis and four 1500-pound wagons.

Chase Motor Truck Company, Syracuse, N. Y. Chase 1500, 2500, 4000 and 6000-pound wagons.

Eldredge, W. E., 221 Columbus avenue, Boston. Couple-Gear electric trucks and Eldredge electric vehicles.

Fischer Company, C. J., 223 Massachusetts avenue, Cambridge, Mass. LaVigne light delivery cars.

Forbes, Walter J., 243 Columbus avenue, Boston. General line of motor truck accessories.

Fryer Company, Charles H., Providence, R. I. Tonneau windshield.

General Motors Truck Company, 753 Boylston street, Boston. GMC 2500-pound, two-ton and 3.5-ton gasoline vehicles and two and six-ton electric chassis.

International Harvester Company of America, Somerville, Mass. IHC wagons.

Kentling & Decker, Newton, Mass. Divine tires and Woodworth tire treads.

Kinney Manufacturing Company, 100 Boylston street, Boston. Kinney pressure distributor for dust laying and heavy asphalt road construction.

Kelly-Springfield Motor Truck Company, Cambridge, Mass. Kelly one, two, 3.5 and five-ton trucks.

Knox Automobile Company, 885 Boylston street. Knox six-cylinder, triple combination hose, chemical and piston pumping engine; four-cylinder combination hose and chemical wagon; Knox-Martin tractors with capacities of 5-6 and 7-20 tons, and for fire department service.

Little Giant Motor Truck Company of Boston, 221 Columbus avenue, Boston. Little Giant one-ton wagon.

Linscott Motor Company, 163 Columbus avenue, Boston. Reo light delivery, 1500-pound and one-ton wagons.

Locomobile Company of America, 700 Commonwealth avenue, Boston. Two Locomobile five-ton trucks and a chassis.

Maddocks, H. Ross, 175 Pleasant street, Boston. Three Stewart trucks with capacity of 1500-2000 pounds and a chassis.

Magill, W. F., 58-60 Brookline avenue, Boston. Universal, 1.5, three and five-ton trucks.

Maguire Company, J. W., 745 Boylston street, Boston.

Three Pierce-Arrow two-ton and three five-ton trucks.

Mattapan Motor Car Company, Mattapan, Mass. Atterbury, 1500, 3000 and 6000-pound wagons.

Milliken, E. H., 68 West Rutland street, Boston.

Myers Bros., New York City. Novelties.

Packard Motor Car Company of Boston, 1089 Commonwealth avenue, Boston. Packard two, three, four, five and six-ton chassis.

Palmer-Moore Company, Syracuse, N. Y. Palmer-Moore 1600-pound wagon.

Parcel Post Equipment Company, 20 Green street, Cambridge, Mass. Parcel post wagons.

R. & L. Company, 915 Boylston street, Boston. Garford two-ton chassis, Garford three and six-ton trucks, Willys Utility chassis.

Rockwell, Inc., C. P., 640 Commonwealth avenue, Boston. Jeffery 1500 and 2000-pound wagons.

Sewell Cushion Wheel Company, Detroit. Special wheels.

Spedolene Lubricant Company, 14 James street, Malden, Mass. Spedolene lubricants.

Stanley Motor Carriage Company, Newton, Mass. Stanley steam 1000, 1500 and 2000-pound wagons and 12-passenger mountain wagon.

Twombly Car Corporation, Avondale, N. J. Twombly light delivery wagon.

Velle Motor Vehicle Company, 16 Amherst street, Cambridge, Mass. Velle one, two and three-ton trucks.

Walter Motor Truck Company, New York City. Walter five-ton front drive chassis.

White Company, 930 Commonwealth avenue, Boston.

reached the Detroit offices of the company in January, and this has now been filled.

No statement has been made by the military officials of Portugal as to the uses to which these machines have been put, but it is believed that they are employed in general transportation service for the army.

KEETONS FOR ARMY WORK.

Maker Supplies Fleet as Part of Hospital and Field Service Equipment.

Although the American Voiturette Company, Detroit, maker of Keeton and Car-Nation cars, is not actually engaged in the production of commercial vehicles, it is interesting to note that it has received substantial recognition from the United States military officials, in that it recently was requested to supply a fleet of Keeton cars for

Fleet of Keeton Cars Recently Supplied to United States Army for Hospital and Field Service.

Four White 1500-pound wagons, 3000-pound wagon, three and five-ton trucks, five-ton dumping truck and patrol wagon.

FEDERAL TRUCKS IN PORTUGAL.

Detroit Manufacturer Has Placed 17 Machines with War Department.

Since March 3, 1913, the Federal Motor Truck Company, Detroit, has placed 17 of its Federal one-ton trucks with the War Department in Portugal. The first machine was ordered a year ago, the idea being to experiment with it and determine its practicability for military service. Evidently, these experiments proved satisfactory, as four more were ordered in September.

Before this second order could be filled, a third, this also being for four, was made in October, and soon afterward, still another order for four machines was received. The fifth order

hospital and field service. An accompanying illustration shows some of these machines ready for duty.

H. H. Newsom, vice president and general manager of the company, states that he has been informed by army men that the French type of construction employed in Keeton cars, with radiator incorporated with the dash, offers peculiar efficiency in army manoeuvring. This is held to be particularly true in crossing ditches and unusually rough country, inasmuch as this placing of the radiator protects it from injury.

It is added that the selection of the Keetons was made only after the most rigorous tests, and the company considers the approval of such exacting judges as army experts the best possible tribute its product could have. It will be noted, from examination of the picture, that these vehicles differ from the standard pleasure car construction, at least in the matter of tire equip-

Interior of Willys Utility Invalid Coach, Showing Attractive Arrangement of Fittings.

men, these being solid rubber blocks, and, of course, in the body installation.

HANDSOME INVALID COACH.

Attractive Body Installation on Willys Utility Chassis for Cleveland Client.

Accompanying illustrations present a handsome invalid coach, or ambulance, recently produced for a client of the Overland-Garford Sales Company, 6604-18 Euclid avenue, Cleveland, O., by the Willys-Overland Company in the old Gramm Motor Truck Company's plant at Lima, O. The chassis is that of a Willys Utility wagon of 1500 pounds capacity, but body work is of special design, and since it is somewhat more elaborate than that of the ordinary ambulance the term invalid coach appears to be more fitting.

The compartment shown in the smaller of the two illustrations is located back of the driver's seat, and entrance to it is by large double doors at the rear, or by a single door at the side as indicated in the larger picture. It will be noted that the invalid's cot and the two chairs for attendants have been designed and constructed with a view to providing the utmost comfort for the occupants. The other appointments include provision for running water, water cooler, wash basin, electric fan,

hot air heat, medicine cabinet, stretchers, sashless drop windows, etc.

The chassis is equipped with a four-cylinder motor, with cylinders cast singly, the bore being four inches and stroke 4.5. This gives a horsepower rating of 25.60 under the S. A. E. formula, but the maker claims it will develop 30 at normal speed. Cooling is by thermo-syphon, ignition by Remy magneto, and lubrication by a self-contained pressure feed system. The clutch is a cone, leather faced, and the selective sliding gear transmission affords three forward speeds and reverse. Brakes are external contracting on the jackshaft, operated by pedal, and internal expanding on the rear wheel drums, actuated by lever. Springs are semi-elliptic, the front members being 45 inches long by 2.25 wide, and the rear, 50 inches long by 2.5 wide. The front axle is an I beam section and the rear, a rectangular section, both utilizing Timken bearings. The standard wheelbase is 120 inches, and the tires, 36 by 3.5 inches.

INTERESTING OMNIBUS BODY.

Maker of Adams Truck Is Prepared to Fit This Type to Its Two-Ton Chassis.

In an effort to provide a practical type of omnibus body that may be available for such service in town and country, the Adams Bros. Company, Findlay, O., has recently produced the 28-passenger vehicle presented in an accompanying

Handsomely Appointed Invalid Coach Body, Fitted to Willys Utility Chassis, Indicating Entrance to Interior at the Side.

illustration. This is fitted to a model E two-ton Adams chassis, made by this concern, the chief departure from standard practise being the lengthening of the wheelbase to 160 inches, to insure the desired stability.

It will be noted that seven seats are provided, each accommodating four people. The space between these is held to be sufficient to permit easy movement of the passengers in entering and leaving, and their comfort is still further assured by the use of substantial leather upholstery. At either side are running boards that are dropped in sections, that portion above the rear wheels being practically at the height of the frame. This arrangement is held to make for extreme convenience.

The roof is of the canopy type, being considerably wider than the seats, and extending backward from a line with the dash with considerable overhang at the rear. This is supported on 10 steel stanchions, five at either side, and affords protection from the sun. In case of storm, ample curtains are arranged so as to be dropped at the sides and ends.

The Adams two-ton chassis is equipped with a four-cylinder, water-cooled motor of the L head type, the cylinders being cast en bloc with bore of 4.125 inches and stroke of 5.25. This gives a rating of 27.25 horsepower under the S. A. E. formula, but the maker's rating is 35. Ignition is by Eisemann magneto. The clutch is a dry disc construction, and the selective, sliding gear transmission affords three forward speeds and reverse. As with all Adams chassis, the radiator is incorporated with the dash, and provision is made for lifting the hood from the front, so as to afford maximum accessibility to the engine.

URBAN ELECTRIC TRACTOR.

Kentucky Wagon Company Produces Machine of Three Tons Haulage Capacity.

Announcement is made by the Kentucky Wagon Company, Louisville, Ky., that it is pro-

ducing an electric tractor with haulage capacity of three tons. This is in addition to the types of electric service wagons manufactured by this concern. The machine is designed to operate in limited space, and has wheelbase of 58.25 inches, although the total length is 154.75 inches, there being an extension at the rear on which the front end of a load carried on a two-wheel reach is supported.

The motor is a General Electric type 1022, rated at 85 volts, 40 amperes, and 1200 revolutions a minute. This is installed transversely in the pressed steel frame just back of the rear axle. The battery, consisting of 44 17-plate Hycap-Exide M. V. cells, is carried on top of the chassis, the forward end of the box supporting the driver's seat. Power is transmitted from the sprocket end of the armature shaft by a Morse silent chain to a sprocket incorporated with the

Adams Two-Ton Chassis, Equipped with 28-Passenger Omnibus Body.

differential assembly of the jackshaft, and final drive is by side chains.

The controller is a continuous torque type, installed in a case in front of the driver, and it affords four forward speeds and two in reverse. Semi-elliptic springs are employed. The front axle is an I section and the rear, rectangular. The wheels are 32 inches in diameter, fitted with four-inch tires. The brake, operating on the rear wheels, is actuated by pedal.

It is maintained that the tractor may be turned in a radius of 15.5 feet. The platform, on which the end of the load is carried, is mounted on a pivot on the frame extension, and the tractor can be driven so that the load when carried on two wheels can be turned in practically its own length. A rope fitted under the extension has a hook at one end, which fastens into the binding chain on the trailer and serves to tow the load.

BECOMES VICE PRESIDENT.

Well Known Consulting Engineer Becomes Identified with Cleveland Concern.

The many friends of Henry Souther throughout the industry will be interested to learn that he has identified himself with the Ferro Machine & Foundry Company, Cleveland, O., and has been elected vice president of that concern. Mr. Souther's experience with the industry has been of the broadest, and he has acted as consulting engineer for a number of years. More recently his work has involved questions of management and system, sometimes leading directly to the field of efficiency engineer.

Mr. Souther graduated from the Massachusetts Institute of Technology in 1887, and began his business and professional career with the Pennsylvania Steel Company, Steelton, Penn. In 1893 he left that concern to become engineer for the Pope Manufacturing Company, Hartford, Conn., in which city he

Henry Souther, Vice President, Ferro Machine & Foundry Company.

opened offices as an independent consulting engineer in 1899. It was in this capacity that he became prominent in connection with the automobile and allied industries, and later as consulting engineer for the Association of Licensed Automobile Manufacturers during the life of that organization. He was president of the Society of Automobile Engineers in 1911.

SHOW IN TIFFIN, O.

Dealers Make Display of Season's Models Amid Japanese Surroundings.

The fourth annual automobile show in Tiffin, O., was held in the Auditorium, March 4-7, and

the interest displayed by the people of that city and vicinity was such as to warrant the dealers in anticipating a decidedly successful year. The interior of the building was made to represent a Japanese garden, several hundred Japanese lanterns being distributed about the wistaria covered lattice work with which the main hall was decorated.

The list of exhibitors, while not so long as in many of the cities of the Middle West, was such as to afford the visitors ample opportunity to inspect the models represented in Tiffin. Among the cars on display were the following: Reo, Mitchell, Paige, Maxwell, Allen, King, Studebaker, Chevrolet, Krit, Regal, Ford, Buick, Parlin-Palmer, Hudson, Overland, Jeffery, Paterson, Empire, Stearns-Knight, Hupmobile, Saxon, Ohio electric and Tiffin, Krebs and Buick trucks.

ANOTHER MERCER RECORD.

Pullen's Speed for 300 Miles Exceeded That Made by Tetzlaff in a Fiat.

It was made plain, in the report of the recent Grand Prize race in Santa Monica, Cal., that Pullen in a Mercer had created a new speed record for this event. It appears, however, that the performance of the Mercer in this contest was even more interesting than would appear from this statement.

It is somewhat well known that the world's road racing record is held by Teddy Tetzlaff, who drove a Fiat car at a speed of 78.5 miles an hour over this same course in May, 1912. Tetzlaff covered but 303 miles, while Pullen's Mercer went 403 miles at a speed of 77.29 miles an hour. According to W. A. Smith of the Mercer Automobile Company, Trenton, N. J., Pullen's average speed for the first 300 miles of the race was 79 miles an hour. This is particularly interesting, in view of the fact that the Mercer is a much smaller car than the Fiat.

APPOINTS SIX REFEREES.

Federation of American Motorcyclists Preparing for the Racing Season.

John L. Donovan, 819 Ashland block, Chicago, Ill., chairman of the competition committee, Federation of American Motorcyclists, announces the appointment of the following local referees for the season of 1914: Ray E. Reed, Jacksonville, Fla.; William F. Hellman, St. Louis, Mo.; John Hohl, Phoenix, Ariz.; William

First Marmon Car, Produced in 1902 and Still in Use on the Road.

C. Voss, Peoria, Ill.; William J. Hall, Montgomery, Ala.; Roy S. Pascal, Newark, N. J. It is probable that others will be named as the season advances.

In connection with these appointments, Chairman Donovan makes the request that those who are planning to hold meets during the coming season communicate with him at once, in order that there shall be no delay with respect to granting sanctions or attending to other necessary matters. He announces his desire to cooperate with clubs and promoters, and asks that they assist him in every way possible.

ALPHA AND OMEGA OF MARMON.

First Car Produced by Nordyke & Marmon Company Still in Active Service.

Accompanying illustrations present the alpha and omega of Marmon cars, made by the Nordyke & Marmon Company, Indianapolis, Ind. The older machine was the first produced by this concern in 1902, while the other picture shows the latest model 41.

This original Marmon car has had a decidedly eventful history. The company was established in 1851, and had gained a reputation in manufacturing fields before the time of its decision to enter the new industry. This car was regarded as a very beautiful creation, and, it may be added, it possessed a number of original features which were destined to represent the accepted standards of the modern automobile.

It was one of the first to have

a side door entrance to the tonneau, selective transmission, affording three forward speeds and reverse, multiple disc clutch with cork inserts, double brakes operating through equalizers, circulating lubrication system, hollow crankshaft, pressed steel frame, tilted steering wheel, etc.

This car originally had a water-cooled, two-cylinder motor, but in 1905 this was replaced by a six-cylinder, air-cooled unit, said to be one of the first six-cylinder engines installed in this country. This motor is still in

good working order, as is evidenced by the fact that it was operated the day this photograph was taken. In the picture, Howard Marmon, president of the company, is at the wheel; at his left is H. H. Rice, sales manager; in the centre of the tonneau is C. C. Hanch, treasurer; on his right, H. C. Shafer, factory superintendent, and on his left, F. E. Moskovics, commercial manager.

The other picture shows F. E. Wing, president of the F. E. Wing Motor Car Company, Boston, Mass., at the wheel of the new light six. He had but recently returned from an extensive tour of New England with a party of friends.

The necessity for larger space and better facilities for handling their increased business has compelled the branches of the H. W. Johnson-Manville Company in Indianapolis, Ind., and Louisville, Ky., to seek new quarters. The former is now located at 408-410 North Capitol avenue and the latter at 659-661 South Fourth avenue. Both of these will include ample warehouse accommodations and service departments.

F. E. Wing and Party of Boston Men in the Latest Marmon Model 41.

NEWS OF THE MANUFACTURER AND DEALER.

The following concerns have been incorporated recently to manufacture or deal in motor vehicles, accessories, etc.:

Elastro Company, Syracuse, N. Y.; \$30,000; to manufacture and deal in compounds for use on tires.

Strite Tractor Company, Minneapolis, Minn.; \$100,000; to build light weight tractors; George T. Strite, Howard J. Bierman, J. S. Clapper, Frank J. Bierman.

American Electrical Company, Portland, Me.; \$1,500,000; to manufacture and deal in electrical and mechanical devices of all kinds, also automobiles and parts.

The Dodge Motor Car Company, Detroit, Mich.; \$1,000,000; to manufacture two-passenger light cars.

Texas Climatic Manufacturing Association, San Antonio, Tex.; \$200,000; to manufacture what will be known as the "Climatic home-grown tires".

Lubricator Company, New York City; \$100,000; to manufacture lubricators for automobile engines; L. R. Balck, David C. Thomas, William C. Ottiwell.

Petty Dirigible Auto Headlight Company, Salt Lake City, Utah; to manufacture headlights.

Universal Lubricants Company, Wilmington, Del.; \$100,000; to manufacture automobile supplies; J. F. Curtin, C. E. Eaton, J. M. Satterfield.

Gay-Streiblich Auto Wheel Company, Little Rock, Ark.; \$125,000; to manufacture a patented automobile wheel.

Willys-Overland Company, Hamilton, Ont.; \$500,000; to manufacture automobiles; J. N. Willys and others.

Brandtjen Motor Car Company, St. Paul, Minn.; \$50,000; to buy, sell and deal in automobile parts and accessories; Henry A. Brandtjen, A. C. Brandtjen, M. L. Brandtjen.

Old Dominion Tire Corporation, Norfolk, Va.; \$10,000; to manufacture automobile tires; J. E. Guy, B. S. Joyner.

Auto Stock Company, Detroit, Mich.; \$50,000; self-starters; William J. Fisher, John Olsen, Mansell Hackett, Fred M. Guy.

Bodock Gasoline Company, Ponca, Okla.; \$50,000; to manufacture gasoline from casing head gas; George L. Miller and others.

Hall-Scott Motor Car Company, San Francisco, Cal.; \$100,000; to manufacture, sell and deal in motor engines.

Amper Control Corporation, Buffalo, N. Y.; \$100,000; to manufacture automobile and engine accessories; E. W. Jones, R. E. Heard, L. C. Kinnlus.

Conway Machine & Garage Company, Boston, Mass.; \$5000; A. E. Stoddard, Albert C. Lary, H. H. Sylvester.

Heeb Auto & Garage Company, Cincinnati, O.; \$10,000; C. M. Heeb, V. Heintz, L. B. Davison.

Associated Garages, New York City; \$110,000; Ira B. Lothrop, Elleen T. Levy, Howard B. Alexander.

North Woodward Garage Company, Detroit, Mich.; \$2500; Maud Brosch, Edwin Brosch, Fred A. Bowers.

Lupfer-Prather Garage of Kissimmee, Kissimmee, Fla.; \$5000.

National Garage Company, Everett, Mass.; \$5000; Frank P. Anthony, Harriet C. Partridge.

Storm King Garage, Cornwall, N. Y.; \$1000; James Lewis, Edward C. Townsend, William Wells.

College Garage Company, Los Angeles, Cal.; \$10,000.

Mount Hope Garage Company, Mount Hope, W. Va.; \$10,000; W. S. Johnson, J. F. Grimet, W. H. Darnell and others.

The 127th Street Garage, New York City; \$5000; W. F. Bullman, G. M. Stevens, H. L. Holly.

Dupre Automobile Company, Columbia, Ga.; \$15,000; to conduct a general automobile and garage business.

Thornton's Garage & Livery Company, Attica, Ind.; \$1000; D. R. Thornton, L. C. Thornton, M. Holmes.

Collingwood Garage Company, Toledo, O.; \$10,000; to conduct a general taxicab business; C. Lemster, O. L. Rankinson, K. S. Lemster, B. Decker, C. L. Deeds.

Hot Springs Garage, Hot Springs, S. D.; \$15,000; James Marty, John S. Fusion, E. R. Juckett.

Eagle Auto Transfer Company, Chicago, Ill.; \$15,000; to operate a garage.

GARAGE AND DEALER.

H. F. Silverthorn, Orfordville, Wis., is making preparations to enter the automobile business, and will convert his general store into a salesroom.

O. P. Coppedge, Pittsburg, Tex., who has been man-

ager of the Pittsburg Auto Company, has withdrawn and will go into business for himself.

The Rutland Motor Company, Ottawa, Ill., has changed its name to the Ingram Motor Company. It now has offices and salesrooms in Rutland, Peoria, Bloomington and Springfield.

William Herron and **Frank Dusenbury**, New Hackensack, N. Y., have opened a new welding plant.

The Phoenix Automobile Supply Company, St. Louis, Mo., has absorbed the Continental Equipment Company. John F. Shuford, manager of the latter, has been made general manager of the consolidated business.

Raoul Sayres, Marengo, Ia., has purchased the interest of W. Ince in the firm of Bishop & Ince. Mr. Ince will retire from the business.

The Automobile Service Association, Philadelphia, Penn., has sold its building at 5123 Swanson street and may locate in a different section.

G. A. Rickenbaugh, Sault Sainte Marie, Mich., has purchased the interest of Walter W. Dennis in the Lock City Auto Company. The company is engaged in a general repairing, overhauling and painting business.

The Winckler Engineering Company, Racine, Wis., a firm of automobile consulting engineers, has been dissolved.

The Louisville Lozier Company, Louisville, Ky., has filed amended articles of incorporation changing the name to the Louisville Automobile Company.

Lattig Bros., Atlanta, Ia., has purchased the business of the Anita Automobile Company.

Wand & Bossard, Beach, N. D., has dissolved partnership. Mr. Wand will continue the business alone.

The McDuffee Automobile Company, Chicago, has absorbed the KisselKar agency in that city. The company now handles four lines, Peerless, KisselKar, Howard and Rauch & Lang.

The Allerton Automobile Company, Allerton, Ia., has purchased the B. & Mc. Automobile Company. The company handles the Chalmers, Buick, Oakland and Ford cars.

Jones & Indra, Green Bay, Wis., which conducted the West Side garage, has dissolved partnership, Carl Jones becoming sole owner. The business will be conducted under the old name and the same line of accessories will be handled. The repair shop is to be overhauled and new machinery installed.

William F. Klatt, Detroit, has purchased the two-story solid brick garage at 3087 East Grand boulevard, for a consideration approximating \$40,000. The building was formerly occupied as a factory and garage by the Wahl Motor Company. The size of the lot is 104 by 100 feet. Mr. Klatt will continue it as a garage, although he will not be active in its management.

Call Bros., Salt Lake City, Utah, has purchased the interest of H. S. Harpster in the Harpster-Baldwin-Call Company on Eighth street. A modern garage will be established.

J. Nichols, Syracuse, N. Y., has taken over the truck end of the Selden business in eight counties. Mr. Nichols is an automobile top manufacturer.

The Hotel Brown Garage, Middletown, N. Y., has been changed to the Post Garage Company, Inc., owing to a change being made in the name and ownership of the hotel, which will be known as the Mitchell Inn. As soon as weather conditions permit a 20 by 40-foot addition will be built to afford more space for storage and the entertainment of tourists. A large machine shop is already in operation.

The United Motor Company, Battle Creek, Mich., has taken over the agency for Ford cars, formerly handled by the American Motor Company.

Ralph Hill, Little Genesee, N. Y., has purchased an interest in the Stevens garage. The business is to be much enlarged and other improvements are contemplated.

H. F. Shaw, Pittsfield, Mass., now operates an exchange for second hand Ford cars, as well as handling the Maxwell cars and Little Giant trucks. Mr. Shaw is located at 983 Dalton avenue.

The Stephenson Taxi Company, Crawfordsville, Ind., of which R. R. Stephenson is manager, has opened for business. The headquarters are on South Washington street.

The Richards Automobile Company is the name of a

new automobile company operating at Black River Falls, Wis.

Harry B. Hartley, Waltham, Mass., has opened an automobile business in that city, as well as conducting the Boston store. He will carry a full line of accessories and supplies.

Allen & Hardy, Monticello, Ark., has opened a supply store. A full line of automobile accessories and supplies will be carried.

Emil Burch, E. E. Rhine and V. K. Robinson have formed the Auto & Sight Seeing Company, at Miami, Fla., with headquarters in the Hippodrome newstand. The equipment consists of 20 cars.

L. J. Hadley and E. O. Merchant, Minneapolis, Minn., have entered a partnership to handle the Menominee trucks, and will be located at 49 10th street.

The Roberts-Toledo Automobile Company, Toledo, O., has taken the agency for the Sherwood automobile trailer.

The Huston-Hanger Auto Sales Company, Washington, D. C., has opened a salesroom at 1119 14th street.

Charles W. Tway, Birmingham, Ala., has opened salesrooms at Avenue D, where he will show Haynes cars.

James Mudie, Des Moines, Ia., is about to branch out for himself and will establish a battery repair business at 413 12th street.

The Shauble-Ferguson Company, Erie, Penn., is the name of a new company which has been formed to handle the Allen car. A salesroom has been opened at 260 East 18th street in charge of R. G. Ferguson. Mr. Ferguson has been in the automobile business for a number of years.

The Commerce Motor Car Company of Illinois, the state sales branch of the Commerce Motor Car Company, Detroit, maker of Commerce business wagons, recently entertained the dealers and sub-dealers throughout that state at a dinner in the Sherman house, Chicago. The purpose of the gathering was to promote the spirit of co-operation and to discuss matters pertaining to the sale of machines in that section. Several executives of the parent company were in attendance.

George Wagner, who has been employed as a tire repairman in Grand Rapids, Mich., for some time, has formed the Central Vulcanizing Company and has located at 228 Ottawa avenue. Mr. Wagner will stock all standard tires and accessories.

The Albia-Ford Company, Albia, Ia., is the name of a new company which was formed to handle Ford cars in that city and vicinity. The new concern is located in the Elder building, recently vacated by the Snow Auto Company. H. J. Longaker is the manager.

WITH THE MANUFACTURERS.

The Croxton Motor Car Company, Washington, Penn., has sold its stock to the Universal Motor Company, and the latter company will manufacture the Universal car.

The F. & H. Wire Wheel Company, Columbus, O., has brought out a new rim for automobile wheels adapted for the use of wire spokes. The factory is at 1432 Parsons avenue.

The Motor Car Spring Company, New York City, is to engage in the manufacture of screw machine products, gas savers and other parts for automobiles and motorcycles.

The Belknap Wagon Works, Grand Rapids, Mich., is preparing to increase its line by making bodies for motor trucks, these being designed and constructed to order.

Gray & Davis, Boston, Mass., has completed arrangements by which its lighting and starting outfits will be sold throughout Europe by the Allgemeine Elektrizitäts

Gesellschafts of Berlin, Germany, commonly known as the A-E-G Company.

Hertz & Co., New York City, is producing a four-cylinder magneto, intended for cyclecar use, and a very compact distributor for battery ignition systems.

The Lovell-McConnell Manufacturing Company, Newark, N. J., is offering to the cyclecar trade the Klaxet, the smallest electric horn, and the new hand-operated Klaxon.

George McCadden, St. Cloud, Minn., is organizing a company to manufacture the piston ring recently invented by him. The company will have \$50,000 capital and will lease a building in Minneapolis. Mr. McCadden is proprietor of the McCadden Machine Works.

The New Process Gear Corporation, Syracuse, N. Y., is erecting a three-story, concrete and steel building, 40 by 100 feet, to provide additional facilities for spur and bevel gear work. The new building is to be absolutely fireproof, with brick curtain walls and concrete floors, and will contain entirely new equipment.

Janney, Steinmetz & Co., Philadelphia, manufacturer of the well known Jasco seamless steel, leakless gasoline tanks, is producing these tanks in sizes and shapes suitable for cyclecar productions.

The Pennsylvania Shafting Company, Westchester, Penn., will erect a new plant for the manufacture of Wright taper roller bearings for automobiles. The cost is estimated at \$150,000. The new structure will adjoin the present plant.

The Rubber Goods Supply & Manufacturing Company,

Recent Dinner Tendered to State Dealers and Sub-Dealers by Commerce Motor Car Company of Illinois.

Akron, O., has changed its name to the Excel Rubber Company. The company is located at 32 West State street, and produces tire accessories.

The Jeffery-Dewitt Company, Detroit, manufacturer of spark plugs, has erected a large addition to its factory No. 3 at Butler avenue and the Grand Truck railroad. The building will be devoted to the first operation in making the porcelains for the plugs.

The Menominee Electric Manufacturing Company, Menominee, Mich., has developed a line of lighting generators for use in connection with cyclecars and is now making shipment.

The Motor Products Company, Chelsea, Mich., will manufacture a V shaped two-cylinder motor for the cyclecar trade, and will shortly be shipping 50 motors daily. The American Distributing Company, Jackson, Mich., will market the output.

The National Forging Company, Hamilton, Ont., has taken over the plant of the Swift Motor Car Company, and will use it for the production of automobile and carriage forgings.

The American Ever Ready Company, New York City, has purchased an entire block in Long Island City, upon which will be erected an eight-story factory, 200 by 300 feet.

The V-Ray Company, Marshalltown, Ia., at its recent annual meeting, trebled its capital stock. Dwight H. Denmead acquired one-third interest in the company. Mr. Sinclair and Mr. Hansen each owning a third interest.

RECENT PATENTS.

Windshield, Richard A. Brine, Boston, Mass.: No. 1,087,104. Filed Oct. 3, 1910.

Multiple-Cylinder Engine, Frederick R. Sunderman, Newburgh, N. Y., assignor to Sunderman Safety Carburetor Company, same city; No. 1,087,151. Filed April 6, 1912.

Power Tire Pump, Joseph H. Templin, Philadelphia, Penn.: No. 1,087,201. Filed May 3, 1912.

Vehicle Trailing Device, Don C. Bryan, San Diego, Cal.: No. 1,087,210. Filed May 24, 1912.

Packing Ring, Edward B. Campbell, St. Louis, Mo., assignor to Sta-Tite Packing Ring Company, same city; No. 1,087,213. Filed July 28, 1913.

Resilient Wheel, John J. Fahrney, Timberville, Va., assignor of one-third to John P. Burke, Harrisonville, Va.; one-sixth to John T. Helbert and one-sixth to Frank H. Driver, Timberville; No. 1,087,226. Filed Jan. 11, 1913.

Vehicle Jack, Edward W. McCarroll, Pittsburg, Penn.: No. 1,087,250. Filed July 7, 1913.

Armor for Pneumatic Tires, Charles Matson, Elizabeth, N. J., assignor of one-half to Ernest Huch and one-half to Rudolph Burkart, Aldene, N. J.; No. 1,087,312. Filed Nov. 4, 1912.

Sleigh Attachment for Motor Vehicles, Halvor E. Hoines, Lake Park, Minn.: No. 1,087,372. Filed April 7, 1913.

Lubricating Means for Two-Cycle Engine, Hermann Lemp, Lynn, Mass., assignor to General Electric Company; No. 1,087,387. Filed April 19, 1913.

Resilient Wheel, Robert A. Nicholson, Russellville, Okla., assignor of one-half to A. S. Nelson, Oklahoma, Okla.; No. 1,087,391. Filed Feb. 19, 1913.

NO BREAK IN PRODUCTION.**Paige-Detroit Motor Car Company Removes to New Plant Without Interruption.**

As stated in these columns recently, the new factory of the Paige-Detroit Motor Car Company, Detroit, maker of Paige cars, has been completed. The concern is now established in its new home, and the methods employed in making the removal were such that there was no interruption of production.

The moving of a factory of any size or kind usually entails the loss of time in actual moving, in starting production in the new plant, and in waiting for stock. In this instance, a whole month was given over to preparation, as a result of which each department was moved separately on a given date and in a manner that would have no effect upon the remainder of the plant.

The motor assembly department, for instance, was given a certain moving date, and on that date was sufficiently ahead of the production in other departments to give it ample time to be running smoothly in the new factory before the rest of the production caught up to it. All new stock for this department was ready; new machines set up, and every detail worked out to lessen the time needed for the change. The same method was applied to each department.

NET PROFITS OF \$7,140,125.**United States Rubber Company Reports Substantial Increase in Tire Sales.**

In view of the change of date for the ending of the fiscal year, from March 31 to Dec. 31, the annual report of the United States Rubber Company, New York City, just made public, covers only nine months. However, the statement shows net sales of \$87,349,692, and net profits of \$7,140,125. This covers the products of various subsidiary companies, engaged in the manufacture of footwear, tires, mechanical and miscellaneous goods.

Included in the surplus of \$1,811,268, are the earnings of certain subsidiaries for the three months ending March 31, 1913, estimated at \$764,657. Deducting this and \$10,939 applicable to minority interests, there remains a balance of \$1,035,672. After adding 4.5 per cent. paid on the common stock, amounting to \$1,620,000, the total, \$2,655,672, represents the amount available for common dividends for the nine months, equal to 7.37 per cent. on \$36,000,000 common outstand-

ing, or at the rate of 9.83 a year. The volume of business done during the nine months was somewhat larger than for the corresponding period in 1912, and the company reports a substantial gain in tire sales through the United States Tire Company.

MRS. HACKETT LEFT PENNILESS.**Well Known Tire Sales Manager's Widow and Child in Extreme Need.**

Circumstances resultant from the death of William J. B. Hackett, sales manager of the Cataract Tire & Rubber Company, who died Dec. 19 at his home in Boston, Mass., are such that The Automobile Journal is impelled to make them known, because there is no doubt that those who knew and appreciated Mr. Hackett in life will be disposed to manifest their friendship in a manner that will benefit his widow and a three-year-old daughter.

Mr. Hackett was an extremely likeable man, enterprising and industrious, and was but 28 years of age when he succumbed to an illness that had continued eight months. His sickness exhausted his resources and when he died Mrs. Hackett and baby were left without even sufficient funds to defray the burial expense. Mrs. Hackett has no people to whom she can turn for assistance, and she is penniless and in great need of substantial aid.

Mr. Hackett was widely and favorably known and there are undoubtedly those who will consider the circumstances in which his widow and child have been placed a reason for contributing liberally to her relief. Those who wish to assist her can send contributions to Paul M. Foss, attorney-at-law, 31 State street, Boston, Mass., or to Mrs. Gertrude C. Hackett, 19 Norway street, Boston.

The Late William J. B. Hackett.

SCOTTISH ASSOCIATION FORMED.

T. C. Pullinger Elected Chairman of Body, Which Has 70 Charter Members.

T. C. Pullinger, Chairman,
Scottish Section, I. A. E.

Members of the Society of Automobile Engineers and others in the industry who met the members of the Institution of Automobile Engineers of Great Britain upon the occasion of their official visit to America in 1913, will be interested to learn that T. C. Pullinger has been elected chairman of the Scottish section of that institution, recently formed in Glasgow. The meeting was held at the Windsor hotel, Feb. 20, and among those in attendance were J. S. Critchley, president of the main body, and F. J. Smith, secretary of the Scottish Automobile Club. The new association starts with a charter membership of 70.

G. E. McCaw was elected honorary secretary, and the following were chosen to act as a provisional committee, with authority to draw up the rules for submission to the council of the parent body: J. F. Henderson, Laurence Bell, G. H. Cutbush, G. Dearie Russel, H. Perrot, J. Carlaw, W. L. Spence and W. J. Thomson. A lecture committee, consisting of J. Iglis Ker, R. J. Smith, Wallace Fairweather and A. F. Sinclair, also was appointed.

NO CADILLAC SIX.

President Henry M. Leland Sees Fit to Correct an Erroneous Impression.

The Cadillac Motor Car Company, Detroit, has no intention of producing a six-cylinder car, according to President Henry M. Leland, who is also president of the Society of Automobile Engineers. The announcement is made to correct an erroneous impression, which Mr. Leland felt had been created. Part of this statement follows:

We have experimented, it is true, with engines of six cylinders; in fact, we have built a number of such cars in the past four years. We have tested them to the utmost, and we have compared them, point by point, with some of the most highly regarded sixes which we had bought for just this purpose. It may be interesting to note, in this connection, that we did not find a single six,

which, in our opinion, outpointed our own in these exhaustive tests. These experiments may have been the basis of rumors that we were to market a six-cylinder Cadillac—but this company has no such intention.

LEAVES HAYNES COMPANY.

George H. Strout Will Retire as General Sales Manager on April 1.

General Manager A. G. Seiberling of the Haynes Automobile Company, Kokomo, Ind., makes public the resignation of George H. Strout, who resigned as district sales manager of the Cole Motor Car Company, Indianapolis, Ind., about a year ago to become general sales manager of the Haynes. It is understood that Mr. Strout will leave April 1, and, although he has not announced his plans for the future, it is expected that he will soon become identified with one of the well known motor car makers.

Mr. Strout is undoubtedly one of the most widely known sales executives in the industry. Shortly after graduating from college, he became identified with the bicycle industry, and since 1899 has been interested in the sale of automobiles. Among the more important positions he has filled with unusual success are the following: President, Western Automobile Company, St. Paul, Minn.; sales manager, Electric Vehicle Company, Hartford, Conn.; sales manager, Apperson Bros. Automobile Company, Kokomo, Ind., and the two already mentioned above.

In making public the resignation from the Haynes company, Mr. Seiberling states that the work for which Mr. Strout was engaged has been accomplished, and

that as a result of his efforts the company has been placed in a much stronger position throughout the country than ever before in the 21 years of its existence.

George H. Strout, Well Known
Sales Executive.

Fifth Avenue, looking north from Washington St., Milwaukee, Wis. Treated with "Tarvia B".

Milwaukee's Experience with Tarvia

Milwaukee has found that ordinary macadam is unsatisfactory under automobile traffic but that its resistance to wear can be much improved by the use of "Tarvia B". This material has been used on plain macadam and on streets which were built with tar binder and needed touching up.

The Superintendent of Street Cleaning, Mr. Charles O. Davis, writes:

I am pleased to say that the results obtained from the use of this Tarvia are very satisfactory.

We have applied this material on tar penetration streets which had begun to ravel, and find that with a very good covering of this material the ravelling was stopped. It gave to the road a nice smooth surface.

Our experience also on waterbound macadam streets is satisfactory and the streets show up fine. One application

sets up the surface, keeping out all water, with the result that the road is kept in good condition. It eliminates the dust nuisance as well.

"Tarvia B" is a special preparation of coal tar, which may be applied to the road either by hand or from some form of modern power sprinkler. The Tarvia percolates into the surface and hardens, forming a tough surface binder. The treated surface sheds water, resists ravelling and automobile traffic, and prevents the formation of dust. As a method of maintenance, periodical treatment with "Tarvia B" is inexpensive and highly satisfactory.

A more thorough method of preserving roads is to build them with Tarvia throughout, in which case the denser grades of Tarvia are used.

TO LIST MORE STOCKS.

Application Made to New York Stock Exchange by General Motors Company.

The General Motors Company, Detroit, has applied to the listing committee of the New York Stock Exchange for the listing of additional voting trust certificates representing \$714,000 par value of common stock, issued since the last application in 1911, and \$583,000 preferred stock, issued since that application. In addition, the company applies for permission to list from time to time \$3,374,200 of common stock and \$3,036,900 of preferred stock, both of which are held at present in the treasury, on notice from the company that the stock has been disposed of. The total amount of stock comprised in this application is \$4,088,200 common and \$3,619,900 preferred.

In this connection, it may be noted that the General Motors stock now listed on the New York Stock Exchange has more than doubled in value since the first of the year. At the close of 1913 the common was quoted around 36, while during the week of March 2 the quotation was

78. The preferred was selling during the last week in December for 78, and during the first week in March at 94.

MANY MEMBERS IN FEBRUARY.

Federation of American Motorcyclists Receives 248 Additions During the Month.

The membership statistics for the month of February, as reported by G. B. Gibson, Westboro, Mass., secretary-treasurer, show that the Federation of American Motorcyclists now comprises a total of 25,917 riders. Two hundred and forty-eight names were added during the month, divided according to states as set forth in the following:

Illinois, 40; New York, 27; Ohio, 24; Texas, 24; New Hampshire, 21; Missouri, 15; California, 14; Pennsylvania, 13; Kansas, 10; Iowa, seven; Maryland, six; Wisconsin, six; Indiana, five; Georgia, four; Massachusetts, four; Oregon, three; Tennessee, three; Arizona, Colorado, Michigan, Minnesota and Montana, two each; Connecticut, North Carolina, North Dakota, South Dakota and Virginia, one each.

Why should the auto business be different from any other business? To my mind it is not, and the sooner it gets down to a horse sense basis the healthier it will be. The day when it was a "game" is gone. The red fire and hurrah period is past. And the companies which stay in are the ones which are going to adopt a hard-headed, close-margined, business-like policy.

You can't short circuit J-M^(MEZGER) SOOT-PROOF SPARK PLUGS Prove it with this test

These plugs are absolutely soot-proof. Prove it yourself by holding one in the flame of a candle or lamp until the end is covered with soot. THEN place it in your engine, turn on the power, and it will positively clean itself. The secret is in the porcelain insulator, or "petticoat," which extends to the end of the plug.

This porcelain becomes so hot at the tip that carbon is burned up the instant it settles. No soot—hence no short-circuit.

Over 400,000 high-class cars are now equipped with the J-M (Mezger) Soot-Proof Spark Plug.

GUARANTEE: The J-M (Mezger) Soot-Proof Plug is backed by a five-million dollar concern with a fifty-five year record for square dealing. If any plug does not give satisfactory service, we will exchange it for a new one. Price, \$1.

Write nearest Branch for interesting Booklet.

**STANDARD
OIL COMPANY**
OF NEW YORK

**"Of the people, by the people,
for the people."**

Lincoln's own words fitly describe the purpose back of the Lincoln Highway. If Lincoln were here and could select his own memorial it would be something useful like this road—something of, and by, and for the people.

Every man cannot be a Lincoln. It is given to all, however, to act in the spirit of Lincoln. The spirit of sacrifice, of devotion to the public good, of pure patriotism.

You would resent the suggestion that you are not patriotic. But what have you done recently to prove it?

Five dollars is a small amount of money. But you can prove yourself a patriot by sending that amount to the Lincoln Highway Association.

There are ten million men in this country who could send this sum and never miss it. And as many more who could send it without hurting. If half this number WOULD send \$5 the success of the Lincoln Highway would be ABSOLUTELY ASSURED.

This Highway will be a magnificent monument to Abraham Lincoln—but as age succeeds age it will be still more a magnificent monument to the common sense, the far-seeing wisdom and the patriotism of the generation—our generation—that built it.

Send \$5 or more today and become a Lincoln Highway builder. Send the Money TODAY while you are in the mood.

If you don't take part in this great work you will have a sneaking feeling of shame all your life whenever the Lincoln Highway is mentioned. Send the \$5 and you will always have a glow of pride in the thought that you helped to adorn your country with this great road stretching like a silver ribbon from blue ocean to blue ocean, binding together states and cities and rural communities in bonds more firm than those of law and language.

Mail \$5 or more today to A. R. Pardington, 2115 Dime Bank Building, Detroit.

Pennant illustrated herewith is in four colors at \$1 per pair. (Rights and Lefts.) Decorate your car. Be a BOOSTER.

You Can't Burn It

—not even with the flame of a powerful blow torch—a flame hot enough to melt iron!

This means that the most intense frictional heat has absolutely no effect on the brakes when lined with

J-M NON-BURN BRAKE LINING

This lining is made of pure Asbestos fibres interwoven with strong brass wires. Not a particle of inflammable or perishable material in it. Oil, gasoline, water, grit, etc., cannot affect it. J-M Non-Burn lining stops a car almost instantly in emergencies. Yet, by applying less pressure, you can stop as gradually as you desire. Name is on every piece. Write nearest Branch for sample and interesting booklet and prices to Dealers.

BUYING AND SELLING MADE EASY

15,000 Trade Interests

READ THE
Accessory and Garage Journal
EACH MONTH

You can secure your monthly audience with all buying and selling heads in all concerns in every branch of the automobile industry through the Accessory and Garage Journal. Such interests must know what you have to offer. All are logical prospective purchasers. They constitute your market and are always looking for lines of merit.

In this magazine the large and small manufacturer has equal opportunity to reach the whole trade and can secure a service equal to that of a trade mailing list and better than can be secured through any other medium.

100 Per Cent. Quantity—100 Per Cent. Quality—Circulation Value.

Every order carries with it a positive guarantee of service stated, and this in any form requested.

Ask how we give concern and product listing under proper classification in Buyers' Guides that have a distribution of more than 1,100,000 copies yearly. This service is free. Our trade mailing list is 100 per cent. active—Do you need it? Details gladly furnished on request.

Next issue March 28th.

PATENTED

¶ You'd certainly object to having a hole bored through your piston head—or, if you found such a hole, you'd plug it. You know you couldn't expect perfect compression with a "holey" piston head. Now, what's the difference whether the leak runs through the middle of the piston head or is down the side between it and the cylinder wall? It's just as much a leak.

¶ Old style, one-piece piston rings with their openings and their poor bearing on cylinder furnish the "hole down the side". They're bound to leak compression and the older they get the greater the leakage. It is to cut out this "down-the-side-leak" through and by the piston ring that *Leak-Proof Piston Rings* are used.

What They Mean to Your Engine

Give perfect compression—prevent gas leakage. Won't let surplus oil get up into the combustion chamber—this means minimum carbonization. Make a cleaner, smoother-running engine. Retain equal tension on cylinder and will not mar smoothness or roundness of cylinder walls.

¶ *Leak-Proof Piston Rings* are made of two pieces and have no unsealed openings; the flange of each section completely plugs the opening in the other. They can't leak. They are absolutely gas-tight. Their two-piece construction on the angle-iron principle—an exclusive and patented feature—makes them stronger than either a one-piece ring or a ring made of more than two pieces. *Leak-Proof Piston Rings*, being made on this two-piece angle-iron principle, are concentric instead of eccentric, and have equal tension on the cylinder walls. They are made of Processed Gray Iron which retains its elasticity under the constant heating and cooling to which piston rings are subjected in service. Softer than the cylinder, yet more lasting than the motor. Made in all sizes—easily adjustable.

VEEDOL

Will Be Your Best Business-Builder

A proven oil made from Pennsylvania petroleum, the result of our 30 years of experience with every kind of lubricating oil.

We have tested it not only by every method known to modern science, but also in actual service under the severest conditions in every standard type of car.

VEEDOL will give satisfaction; it will bring in the repeat orders, because your customers will find that it affords the most nearly perfect lubrication with the least carbon deposit.

We do not claim that VEEDOL will eliminate ALL friction; that as it burns it will deposit absolutely no carbon—there never will be a PERFECT lubricating oil.

VEEDOL is the most nearly perfect that has ever been produced. Its gravity, viscosity, flash and fire tests; its lubricating value at operating temperatures, make it the ideal internal combustion engine lubricating oil.

Car owners will learn these facts as soon as they give VEEDOL a trial. They will be asking for it everywhere.

We want a responsible representative in every automobile center of the country. There's a big business opportunity for you if there is no agent in your vicinity. Write at once for particulars of our new selling plan. We back up our representatives with the most intensive consumer advertising campaign ever put in operation for a lubricating oil.

66 Miles High

OUR 1914 production of 50,000 cars piled one on top of the other, would reach 350,000 feet or 66 miles in the air.

This is over 355 times as high as the Eiffel Tower in Paris, which is the tallest structure in the world.

This is over 466 times as tall as the Woolworth Building, in New York, or 630 times as high as the Washington Monument.

Also this is over 432 times the length of the Imperator.

Such figures are dazzling, but they help to prove the one great big point which we have always endeavored to drive home—the economy of producing automobiles in great quantities. Manufacturing, purchasing and marketing on a 50,000 car basis is infinitely less expensive than on the thousand car basis.

Catalogues free on request.

J. H. S. SHOCK ABSORBERS

are a revelation as well as a revolution in spring suspension.

Their sensitiveness of action **AUTOMATICALLY** takes up and destroys jars and jolts, either heavy or light, and to the occupant of a car it seems like riding on air—fairly floating through space.

Vibration is eliminated, thus giving long life to tires, motor, transmission and other components. In consequence greater speed is possible, as the car does not tend to skid or roll. The mechanical principle of the J. H. S. Shock Absorber is as scientific as that of a hydro-carbon engine. A cylinder and piston are used to insure durability, there being no fragile parts to wear or easily get out of order. The piston acts in harmony with coiled springs which destroy all shocks.

WHEN OWNERS MUST BUY SELLING IS MADE EASY.

The 20,000 Readers of the April 25 Issue of The Automobile Journal Will Represent a Wonderful Market Because Their Requirements Makes it Necessary for Them to Purchase.

Stimulate Your Dealers' Business. Create a Demand for Your Lines Among Owners, Operators and the Trade. Quality, Quantity, and 100 per cent. Circulation Value Buyers Will Read

THE ANNUAL OVERHAUL AND EQUIPMENT NUMBER OF

The April 25 issue of The Automobile Journal, while a regular edition, will, as is customary at this season of the year, specialize in the overhaul, repair and equipment of the pleasure motor vehicle.

Preparing the car is the one subject that is claiming the attention of every car owner and operator at this time. Practical and comprehensive discussions dealing with all that is necessary in the overhaul, replacement of parts and equipment is eagerly sought by owners, operators and the trade.

Manufacturers of tools, machinery, garage equipment, supplies, accessories and those conveniences economizing in time and labor should give careful consideration to this edition. It will reach those who own, operate and maintain their cars and at a time when they are in the market and are spending money.

The following partial synopsis of contents emphasizes the extent that the April 25 issue will deal with the above subjects and make clear the value of this edition to readers and advertisers alike:

Value of the overhaul and method of ascertaining its extent.
What the owner may accomplish and suggestions for preparation.
How the repair bill may be considerably reduced.
Tools, supplies, etc., necessary in the work and how to select them.
Preparing the cooling system, cleaning and repairing.
Overhauling the power plant and replacing worn components.
Cleaning and adjusting carburetors and fuel tanks.
Attention necessary with lubricating systems.
Cleaning, adjusting and timing magnetos.
Cleaning and adjusting the transmission and replacing worn parts.
Importance of a thorough overhaul of the steering gear.
Relining brakes and inspection of the rear axle.
Steps necessary in placing the storage battery in service.
Electric lighting and starting equipment for heavy and Ford cars.
Accessories and equipment making for comfort and convenience.

Ability If You Have a

Duelec Vaporizing Primer and Economizer

(Patent Applied For)

PRIMER ONLY—\$5.00

PRIMER AND ECONOMIZER—\$7.00

Attaches to intake manifold, at any location, in any position, operates from switch on dash. Half hour installs it.

OPERATION.

Turn on switch, give engine quarter turn, either by cranking, or by starting mechanism. A drachm of fuel (gasoline, kerosene, denatured alcohol, etc.,) is drawn from main feed line, enters heating chamber, is vaporized, inhaled by cylinder. The first spark explodes this **HOT, FUMING, VAPORIZED** charge. **YOU'RE OFF.**

The economizer begins operating as the engine speeds up. Feeding **HOT** air, resulting in great reduction of fuel consumption, vastly increased power and speed.

ADVANTAGES OF DUELEC.

No extra fount of gasoline, or risky mixtures required.

No incessant, tiresome, dangerous cranking.

No unnecessary, expensive spinning by self-starters.

No complicated mechanism. Works automatically.

SUPPLIES HOT, FUMING, VAPORIZED FUEL, for starting, and **HOT** air through economizer.

FORD OWNERS.

DUELEC operates from **MAGNETO**. Uses only $\frac{1}{4}$ ampere. We will refund price, if it does not prove superior to any device to promote easy starting, and increase power with decrease of fuel consumption.

MOTORISTS. Demand **DUELEC** of your dealer, or we will send direct upon receipt of price, all fittings included. With order state size of gasoline feed line, source of current and voltage of current. Great satisfaction guaranteed. 6, 8, or 12-volt battery supplies current.

DEALERS. **DUELEC'S** all round superiority, ease of installing, universal adaptation, and low price, makes it a **BEST SELLER**.

Starter, Engine, Cyclecar and Auto Manufacturers.

Send for **DUELEC**. We will submit one for trial and comparison.

Have your engineer test and compare with anything on the market.

Place your order accordingly. Patents allowed and pending.

Make remittance to order of **U. S. Traub**.

THE AUTOMOBILE JOURNAL PUBLISHING COMPANY
Times Building Pawtucket, R. I.

PUBLISHER'S COMMENT.

The Annual Overhaul and Equipment Number of The Automobile Journal will be issued April 25. In preparing the special articles on these subjects particular attention will be paid to the needs of the new owner—the man who is approaching the period of the annual overhaul for the first time—and the discussions will present the various steps in a manner devoid of technical terms so that the details of the work may be understood readily by the novice. With respect to the equipment of the machine for the active driving season, effort will be made to include all the latest accessories and fittings, with special reference to those installations which have been developed for equipping older models with those devices making for comfort and economy now supplied regularly as standard equipment. Order your copy now—direct or through your news dealer.

Complete Specifications of gasoline pleasure cars made in America for the 1914 season were published in the Feb. 25 issue of The Automobile Journal. Equally complete data respecting commercial vehicles were presented in the March issue of

Motor Truck, published by this company. In anticipation of an increased demand for these numbers, extra copies have been prepared, and readers who are interested in these details may be supplied, at the regular rates—The Automobile Journal, 10 cents; Motor Truck, 20 cents.

Particular Attention is drawn herein to numerous commercial vehicle installations, supplementing the review of the Boston truck show, and it seems of interest to add that each issue of Motor Truck contains invaluable information for the business man who is contemplating the purchase of such equipment. All the regular departments of the Journal have also been retained in this number, including New Accessories (page 35), Suggestions for New Owners (page 42) and Correspondence with Reader (page 53).

Do Not Overlook the Buyers' Guide on pages 87-96, inclusive, when in need of anything new in cars, accessories, supplies and fittings. The concerns listed are wholly reliable and worthy of your consideration. And when corresponding with advertisers please mention The Automobile Journal.

VOL. XXXVII, No. 4

MARCH 25, 1914

Price, \$1.00 the Year

TRUCK SALES AGGREGATE \$1,000,000.

Boston Display, Only Commercial Motor Vehicle Exhibit of National Prominence This Year, Proves Right to Classification with Annual Pleasure Car Show.

PRODUCTIVE of consummated sales that were estimated to aggregate fully \$1,000,000, and of prospects that ought to increase this total very largely, as well as stimulating interest that will undoubtedly result in profitable business, the third annual show of service vehicles of the Boston Commercial Motor Vehicle Association, which was concluded at Mechanics' building the evening of March 21, was from every point of view a success. This exhibition, the national

display of motor trucks and wagons, and the only exploitation of machines that will be made in this country this year, was attended by approximately 50,000 persons, or an average of 10,000

daily, which is undoubtedly a record for a show of this character.

Viewed from any aspect the show was all that could be desired — from the standpoint of the management, the organizers, the exhibitors and the visitors—it being complete and representative of the industry and including practically

General View of Grand Hall from the Balcony, Showing the Principal Truck and Wagon Exhibits on the Main Floor.

The Main Aisle in Grand Hall, Looking Through the Exhibit of the White Company, Toward the Stage, on Which Was the Packard Display.

every type of vehicle recognized as a commercial proposition. The exhibit was comprehensive from the fact that it included the latest developments of types and models, and was also noteworthy from the fact that there was not a freak construction displayed. As a matter of fact one might say that the show was of designs that had been proven and their worth established, and from this aspect demonstrated to the visitors that the industry has settled down to building vehicles that are thoroughly dependable so far as principles are concerned, and the variance is frequently in quality of material and workmanship rather than in designing.

The Boston show attracted to it people from all sections of New England, New York, New Jersey and the British provinces, and with the majority of the visitors the interest was keen. The exhibitors without exception were represented by the most expert of their salesmen and often by factory representatives, and no opportunity was lost through absence of selling force, which has in past years been a fault with many of those making display. The necessity of having men always available to meet the visitors was understood and this was

one of the reasons why the exhibition was so productive.

In all there were 34 different makes of machines shown, there being 32 makes of gasoline vehicles and two of electric and one steam, one concern producing both gasoline and electric. The total number of complete chassis, with or without bodies, was approximately 150, and with rare exceptions

no display was made of components or special parts, the belief being that the public is sufficiently informed relative to constructional detail and does not need specific demonstration of machine work and material. In some instances, however, where a new principle is employed, specimens of the construction were shown for the purpose of the better informing those who desired instruction.

The exhibition was confined principally to the main floors of Exhibition and Grand halls, but the balconies of each was open for the convenience of those who desired to be apart from the exhibits or to listen to the concert programmes. The showings of accessories were comparatively few, these being generally of lubricants and the like, while in one corner were several power

The Main Aisle of Exhibition Hall, Looking Toward the Principal Entrance, Showing the Kelly and I. H. C. Exhibits in the Foreground.

The Stand of the Whitten-Gilmore Company, at Which Was Shown the Exhibits of Standard Trucks and Federal Wagons.

launches which had been displayed by a concern that profited largely by being represented.

Of decided interest was the construction of the motors used, and two only showed two-cylinder engines, these being the Autocar and the I. H. C., the latter built by the International Harvester Company. These two concerns have utilized this form of motor constantly and have practically continued one design each, though the I. H. C. engine is cooled by water or by air as desired. Both these motors are the horizontal opposed types. The Merz parcel post delivery, and the Parcel Post light wagon, have vertical, two-cylinder, air-cooled motors in which the cylinders are set at an angle of 90 degrees. The Chase Motor Truck Company had two types of three-cylinder, air-cooled motors, and the Palmer-Moore delivery wagon shown was fitted with a three-cylinder, water-cooled motor. Both Chase and Palmer-Moore engines are two-stroke cycle. The Palmer-Moore motor is also built air-cooled, and the Chase company builds a four-cylinder, water-cooled engine. All other motors shown were the conventional four-cylinder, four-cycle, vertical, water-cooled types, the variance being with

reference to bore and stroke, valve location and lubrication.

Two new worm and gear driven machines were shown, these being the Atterbury 3000-pound wagon and the three-ton Chase truck, and these machines are distinctive from the fact that in both the designers have followed foreign practice and abandoned

the use of radius rods, driving the vehicles through the rear springs. The same principle is applied in both constructions. The forward hanger of the rear spring is heavy and on this the spring is mounted with a large eye that is formed from the master and long leaves, but the rear end of the spring is shackled so as to have free movements. The Atterbury spring is seated on the rear axle, but the Chase spring is underslung. Both, however, are comparatively flat, so that the driving thrust may be as nearly horizontal as is possible. This construction necessitates a very long hanger in the Chase truck. The Universal, the other worm and gear drive machine shown, has been constructed for about a year and a half.

The Walter five-ton truck shown was con-

The Combination Tank Truck of the Kinney Manufacturing Company, Adapted for Street Watering, Oiling or Tar Application on a Peerless Chassis.

The Exhibit of the Knox Automobile Company, Grand Hall, with a Knox-Martin Tractor and Trailer with Dumping Body.

structed under the Latil patents, and with such adaptations as are believed desirable for American service. This is a front wheel driven machine and the drive is from a unit power plant by a countershaft that drives spur pinions meshing with internal gears carried in housings on the front wheels. The rear wheels roll free and may be shod with steel or rubber tires, but the forward wheels are fitted with block shoes. The forward springs are fitted with centre bands that are shrunk on while hot, which insures against movement at the spring saddles. The rear hangers are fitted to mount the springs with bronze bushed eyes on heavy bolts, but the forward ends are shackled, this construction taking the deflection and the engine torque when starting. One of the innovations is the connection of the foot or service brake to act on the four wheels, and still greater clamping effort is applied to the rear wheel brakes by the use of the emergency hand brake. The four-cylinder block motor, clutch and gearset, assembled as a unit, is mounted at the forward end on a trunnion carried on the front frame cross member, and suspended near the rear end from a curved steel cross member by four large bolts. By removing the front cross frame

member and the four bolts, and breaking the exhaust, water, fuel and ignition connections, the chassis may be pushed back, or the power plant may be hoisted from the frame. The machine is made in three, four, five, six and 7.5-ton capacities. The company is also making a four-wheel driven

tractor in sizes up to 12 tons hauling capacity. this being steered by four wheels as well. The rear wheels are driven in precisely the same manner as the forward wheels, a propeller shaft extending to a differential of a second countershaft mounted above the rear axle. This tractor is expected to carry a four-ton load and draw two four-ton trailers.

The Merz parcel car was the only friction machine exhibited, this being a cyclecar chassis fitted with a box behind a cab that will seat a single person. The Stanley steam vehicles and the Buffalo and the GMC electric machines were practically unchanged from the designs of a year ago. The fire apparatus shown by the White, Knox and the I. H. C. companies was of combination types, and the Knox-Martin tractor with a converted horse steam fire pump completed the

The Display of the General Motors Truck Company in Grand Hall, Showing the Special Body Built for the Animated Advertising Company.

exhibit of motor driven apparatus of this nature.

One of the interesting exhibits was the new Kelly five-ton truck, which is practically the same design as the smaller machines. The Little Giant delivery wagon shown is an entirely new design, this having a four-cylinder, water-cooled, en bloc motor, a pressed steel channel section frame, larger wheels and tires, and many other details of relative lesser importance. The four and six-ton Packard machines were displayed, these following practically the standard design of the company. The Pierce-Arrow two-ton machine was exhibited for the first time, but this has been in the market for six months or more. The Velie new one-ton machine was shown with and without body. This is a conventional design, having a 45 horsepower four-cylinder motor with constant level circulating lubrication system and Bosch dual ignition, multiple disc clutch, selective type transmission gearset, and a propeller shaft to a full floating rear axle. The motor, radiator, clutch and gearset are carried on a sub-frame. The chassis is equipped with an electric starting and lighting system.

One of the incidental constructional details of interest was the use of the Daimler leather disc universal or flexible joint between the clutch and the gearset in the Stewart machines and at the ends of the driving shaft of the Chase two-ton truck, between the clutch and the gearset, and at the ends of the propeller shaft of the Chase three-ton machine.

The display of bodies was unusually large and complete, ranging from 3000 to 10,000 pounds capacity with the dumping equipment, practically all of the machines shown being fitted with power hoists. Some admirable special body work was exhibited, including the panel types with individual decorations, and a unique display was a body built for the Animated Advertising Company with panels of glass on a GMC chassis, in which animated advertising is

to be shown by means of reflected electric light supplied from a large storage battery. This is one of a number of gasoline and electric machines that will tour the country. The progress made in body building was marked, and this equipment attracted much attention.

ARGO PLANT IN RACINE.

Latest Briscoe Organization Has Secured Factory for Production of Motors, Etc.

While it was announced recently that the Argo Motor Company, of which Benjamin Briscoe is one of the controlling forces, was to locate in the vicinity of New York City, the latest information respecting this concern is that it has ac-

The Palmer-Moore Delivery Wagon, Equipped with a Three-Cylinder, Two-Cycle, Water-Cooled Motor and Four-Post Express Body.

quired the plant formerly occupied by the G. W. Jagers Company in Racine, Wis. The company was organized for the purpose of producing a low priced, light weight pleasure car, practically in the cyclecar class.

It is explained that the Racine factory is to be used for the manufacture of motors and transmissions. It affords a floor space of about 125,000 square feet. It is added that machinery valued at \$35,000 will be installed and that work on these components will be begun shortly. It is also understood that the radiators will be produced in the plant of the Briscoe Motor Company in Jackson, Mich. Evidently it is intended to locate the assembling plant in New York State, unless the plans have been changed.

DAWSON AND A MARMON.

Two Well Known Names Added to Entry List for the International Sweepstake Race.

According to the latest information from Indianapolis, Ind., Joseph Dawson will drive a Marmon car in the fourth annual 500-mile race for the international sweepstake award on the speedway in that city, Memorial Day. The car is entered by a private individual and not by the Nordyke & Marmon Company, its maker, since that concern announced its withdrawal from racing some two years ago.

It was in a Marmon car that Ray Harroun took the first 500-mile race in 1911. Harroun is interested in the Maxwell team this year, although it is stated that he does not intend to drive in the event. Dawson won the second race in 1912, at the wheel of a National car, setting a new record for the event, which was not exceeded last year by Jules Goux in a Peugeot. Goux and his Peugeot are entered again this year. As a result of this latest entry interest in the forthcoming event has been increased very materially, since representatives of the winning combination in each of the previous races will be taking part.

BIG BUSINESS FOR REO.

Record Mark Attained in Both Production and Sales at Factory in Lansing, Mich.

The demand for Reo cars and trucks is keeping both factories of the Reo organization, the Reo Motor Car Company and the Reo Motor Truck Company, in Lansing, Mich., working overtime of late. Last year, at this time, 40 Reo cars a day was regarded as the limit of production. With the buildings which were added recently, and the increased factory facilities, the production has gradually increased to 65 a day, and there have been many busy days during the past few weeks when the shipments have run up to 90 cars a day. It is stated that there are over 2000 orders already on the books for delivery during April.

An immense amount of new machinery was installed last fall. One large building was added to the Reo factory for storing cars, but that structure has been empty practically all of the time. This appears to have been the only mistake made by the Reo organization, since it failed to properly gauge the popularity of the Reo the Fifth cars, and the ability of the sales depart-

ment to place these machines as fast as produced.

The truck end of the Reo business has witnessed much the same success. The officials of the company state that it is safe to predict a business in this field double that of last year, which was a new record for the company.

NEW OFFICERS ELECTED.

United States Rubber Company Adds a New Name to the Directorate.

The annual meeting of the United States Rubber Company was held March 17, at which the number of directors was reduced from 21 to 20, no one being elected to succeed the late J. Howard Ford. All of the retiring directors were re-elected, with the exception of Commodore E. C. Benedict, who is withdrawing from all business connections. He was replaced by Col. Samuel M. Nicholson of Providence, R. I., president of the Nicholson File Company and the Providence Screw Company.

At the meeting of the directors March 20, the following officers were elected for the ensuing year: President, Samuel P. Colt; vice president, James B. Ford and Lester Leland; vice president in charge of tire and mechanical goods department, Elisha S. Williams; vice president in charge of footwear, Homer E. Sawyer; vice president in charge of development department, Raymond B. Price; treasurer, W. G. Persons; secretary, Samuel Norris, and assistant secretary, John D. Carberry.

ORGANIZE NEW COMPANY.

Two Well Known Ignition Salesmen Establish Headquarters in Washington, D. C.

Charles Rubel, for a number of years connected with the Connecticut Telephone & Electric Company, Meriden, Conn., has resigned as sales manager of that concern. With Elmer H. Hohenthal, formerly connected with the Bosch Magneto Company, he has organized the Charles Rubel Company, with headquarters at 1312 14th street, N. W., Washington, D. C., for the purpose of acting as manufacturers' representative.

A two-story building has been secured and will be completely equipped for handling ignition and lighting systems and carburetors. This will include a good sized machine and electrical shop, in charge of Percy R. Haycock, for four years superintendent of service for the R. M. Owen Company, New York City.

SPARK PLUG ASSOCIATION.

A Statement of What It Expects to Accomplish for Such Manufacturers.

As previously stated in these columns, the spark plug manufacturers recently formed a national association, which now has a membership representing 80 per cent. of the makers. Work already has begun looking toward the correction of various trade abuses, which are held to have developed through the wonderfully fast growth of the industry.

Another most important object of the association is to bring about a better realization on the part of the individual manufacturers of the trade mark value it is possible to create in their plugs. This is expected to establish friendly competition along lines which will undoubtedly result in the improvement of the entire product.

are wrapped so as to leave a clear circular space in the centre, are to be measured on the outside diameter for length and the circumference of the casing as the girth.

In measuring a tire which is wrapped so as to form a circular shaped parcel without a perfectly clear space in the centre, the outside diameter of the parcel is to be taken at the length and twice the diameter and thickness as the girth.

PIERCE-ARROW'S BIG MILEAGE.

Montana Owner Reports 170,000 Miles of Service Under Unusual Conditions.

An accompanying illustration shows a Pierce-Arrow car, made by the Pierce-Arrow Motor Car Company, Buffalo, N. Y., which has seen 170,000 miles of service, according to a recent report from the owner, the Wm. H. Brown Company of

Pierce-Arrow Touring Car That Has Seen 170,000 Miles of Service Under Unusual Conditions with Montana Real Estate Concern.

J. Waterman Fischer, Jr., is secretary of the association and he also is sales manager for the Silvox Company, New York City, maker of the well known Bethlehem Five-Point plug. He will be glad to receive any communications regarding the new association at his office, 60 Wall street, and will furnish detailed information whenever requested.

TIRES BY PARCEL POST.

Postmaster-General Burleson Issues Order Permitting Transmission in This Manner.

Automobile tires may be dispatched by parcel post, according to an official order issued by Postmaster-General Burleson, countermanding a previous order forbidding their receipt as mailable matter. Under this latest order tires which

Hobson, Mont. The conditions under which this machine has been operated are decidedly unusual, and the report has additional interest because of that fact.

The Brown company is in the real estate business, and has large tracts of wheat and alfalfa lands for sale. In showing prospective customers over the property, it is necessary to cover a good deal of territory. There are all kinds of roads, but often whole days are spent looking over lands where there are no roads at all. This means that the car is called upon to traverse rough prairie, stubble and plowed fields.

An official of the company says the car often is overloaded, and adds: "I do not know of any other make of car that will stand the hard work we give them. We have had a number of other makes, but have never been able to get the mileage that we do out of our Pierce-Arrows".

GROWTH OF MOTOR TRUCK INDUSTRY.

A Few Examples Indicating the Wide Field of Service for the Mechanical Transport and the Manner in Which the Manufacturer Seeks to Co-Operate with User.

WHILE it is practically impossible to obtain reliable statistics indicating the exact number of commercial motor vehicles in use in America today, a conservative estimate would place the figure at somewhere between 50,000 and 75,000. Probably the grand total is even larger than this, since a large number of converted pleasure cars are included in the list, and it is extremely difficult to draw a line, other than by defining a commercial vehicle as a machine that is used for business purposes. Obviously, this definition is too broad, but it impracticable to limit statistics to the one phase of mechanical haulage. Elsewhere in this issue will be found discussion dealing with specific features, and the purpose in this instance is to direct attention to

steam, but as yet this type of road vehicle has not secured the same prominence in America that it has abroad, although there are a few steam trucks in operation in this country.

Spirit of Co-Operation.

The first power wagons were pleasure car chassis equipped with service bodies. The industry had not yet learned that it was necessary to build a vehicle which must be suited to the work it was expected to do. If the manufacturer was not aware of this, it hardly could be expected that the business man was better informed. It may be added, however, that both manufacturer and user soon discovered that something was radically wrong. Much has been accomplished in these few years, and today the business man

A Portion of the Fleet of Gasoline Trucks Utilized by Frederick Loeser & Co.'s Department Store, Brooklyn, N. Y.

machines employed in what might be termed general utility service.

Because of the magnitude of the automobile industry, and of this branch in particular, it is possible, in the space available, to do little more than suggest a line of thought. Within the past few years the widespread interest in motor trucks and business wagons has afforded sufficient opportunity for all to become more or less familiar with the fact that such vehicles are utilized for an ever growing number of purposes. The thoughtful observer cannot stand on the street corner in hardly any city or town in the United States without discovering some new field in which the gasoline or electric motor has won a place. The writer had almost included

who desires to secure the superior advantages of the mechanical transport, readily obtains the heartiest co-operation of the producer, to the end that he shall be supplied with that type of vehicle best suited to his individual needs.

It would seem safe to say that there is practically no field in which the motor truck has not established itself, and yet, so diversified are the needs of the industrial world, manufacturers are continually being confronted with new problems. Usually, however, these involve the body equipment rather than the chassis construction, and, because of this factor, it is the usual practise of the manufacturer to list but a few standard body designs, leaving the matter of special bodies to be solved by a maker who specializes in that field.

Pierce-Arrow Five-Ton Truck Which Does the Work of 11 Horses in Service with Capitol City Lumber Company, Hartford, Conn.

The reason is not far to seek. The necessary equipment and capital required to meet every need of this nature would seriously handicap the facilities for producing chassis and work against that proper service which the present day motor truck maker seeks to render.

Department Store Delivery.

Some specific examples of installations have been selected as indicating the various lines in which motor trucks have been utilized with wide success, these being presented in accompanying illustrations. Frederick Loeser & Co., Brooklyn, N. Y., may be cited as an example of the department store delivery service. This concern had 300 horses some nine years ago. At the time this photograph was taken, 204 of these had been replaced by 28 electric and 14 gasoline machines. It follows that a store located in that city must have secured much additional business in the interim, so that the 42 motor vehicles were required to do a great deal more work than the 204 horses they replaced. The company keeps a careful record of its machines, and knows exactly what to expect of each. The plan may differ materially from that in use by other concerns throughout the country, many of whom utilize fleets of wagons of

a similar character.

The difficulties presented in department store service are by no means so many nor so varied as those which are confronted in many other fields. Those who have had experience with motor vehicles are convinced that there is little question as to the economy that can be effected, but

to secure the utmost economy it is necessary that the machines shall be worked as nearly as possible to their fullest capacity. This involves the means for loading and unloading. With the department store, the former is solved by arranging the shipping facilities so as to secure the greatest efficiency. It would prove impractical to discuss this phase of the subject to any length in the space available here.

Lumber and Coal.

Both loading and unloading present problems in the lumber business. In the case illustrated the chassis platform is fitted with rollers. The lumber is loaded on a four-wheeled wagon in the yards, while the truck is absent making delivery. Upon its return the load is transferred to the truck with very little loss of time. Of course the unloading is simplified in the same

Knox-Martin Tractor Hauling Nine Tons of Coal in Service with M. S. Converse Company, Springfield, Mass.

Express Companies Are Large Users of Motor Vehicles, Although Not All Are Electrically Propelled.

manner. This particular truck shows an efficiency equal to that of 11 horses, and an economy represented by a cost of 36 cents a 1000 feet as compared with 75 for a two-horse team, according to the figures of the company.

Other concerns have solved their specific problems in other ways. Generally speaking, however, it has been determined that the most satisfactory method involves the use of extra wagons of some character. One lumber dealer in Cambridge, Mass., utilizes electric trucks, the load being arranged on two-wheel carts, the front end being carried on the truck itself. Another large dealer in Providence, R. I., who makes a specialty of handling heavy mill construction lumber, uses a Knox-Martin tractor and specially designed wagon, the lumber being loaded by huge cranes. In every instance it has been demonstrated to the satisfaction of the user that the motor vehicle is both economical and efficient.

Coal may be loaded by overhead chute, but special bodies are often necessary to facilitate quick dumping of the load. An example of such equipment is found in the combination utilized by the Springfield

house, as illustrated herewith. The body was specially designed to hold five tons, and the interior walls slope toward the centre, so that it is a simple matter to fill a basket by opening a slide at the side. The motive power is a Knox-Martin tractor, which may be available for a large number of purposes. That it is capable of hauling heavy loads

is exemplified by the photograph, which shows a load of nine tons, four tons being carried in bags on top of the main load.

In this particular instance, the custom is to carry coal from the street, in making household deliveries, and this practise cuts down the efficiency of the equipment somewhat. Where it is possible to make delivery direct, either by dumping the load through a hole in the sidewalk or into a chute, other plans may be followed, although the tractor equipment shown is available for this purpose. Some body makers provide sectional bodies, each section holding a ton of coal and each dumping separately, so that it is possible to make several deliveries along a route without loss of time in returning to the yard.

Peerless Four-Ton Machine That Paid for Itself in Seven Months Moving Household Goods with Concern in Worcester, Mass.

Federal One-Ton Truck Which Supplants Four Horses in Milk Delivery at a Daily Cost of \$3.50 for Farmer in Bloomfield, Conn.

There are unlimited possibilities for the general teaming and transfer companies. Within the past two years trucks have been used to decided advantage in long distance moving work, where the load is that of household goods. It would prove decidedly interesting to consider this topic at some length. The example cited depicts a Peerless truck in service with Henry Masse, Worcester, Mass., who states that he ceased to keep track of the expense of the vehicle after it had been in service some seven months, since it had paid for itself and showed a handsome profit on the investment at that time. That it is possible to secure satisfactory returns on the investment in short hauls of the general transfer character is borne out by the very large number of trucks and delivery wagons, both gasoline and electric, owned and operated in many cities by the established express companies.

alone. He owns 10 horses, but they do farm work only. And the truck handles a number of odd jobs, besides delivering milk, among them being the oiling of 32 miles of road in the towns of Bloomfield and Grandy.

Extending Business Radius.

The Lincoln Safety Deposit Company finds its fleet of six General Vehicle electric trucks of decided value in securing new customers. Its business is that of maintaining vaults for the safe keeping of property, and the machines are utilized in transferring the goods between the vaults and the homes of its patrons. They cover a radius which embraces Stamford, Conn., a round trip distance of 35 miles.

The Maine Creamery Company has utilized trucks in the delivery of ice cream over a wide area for several years. Last year it produced 200,000 gallons. Not only are the trucks em-

Four of the Fleet of Six General Vehicle Electrics in Service with the Lincoln Safety Deposit Company, New York City.

Packard Trucks Engaged in Hauling Ice and Delivering Ice Cream for Maine Creamery Company, Providence, R. I.

ployed in the delivery of this product to stores and other consumers, but other trucks are used in hauling the ice from its storage plants. The example indicates the availability of motor vehicles in both fields, although in this instance the ice haulage is for private consumption rather than household delivery.

In the latter service, motor trucks have been found of exceptional value in hauling ice from the ice houses to a central distributing point, there to be transferred to horse drawn wagons for house to house delivery. This plan also is followed in numerous other lines, notably the delivery of groceries, etc., in the suburbs, and sometimes gasoline machines are utilized for this long haul work, while electrics are employed in the service where frequent stops are to be made.

In Contract Haulage.

But one example of steam haulage is shown, this being the installation employed by the Terminal Transport Company, New York City, in undertaking contract work in that city and vicinity. The machine is an English product, as are the trailers. The former is capable of carry-

ing 7.5 tons, while the trailers each hold three tons. In practise one trailer is left at each end of the line, while a third is being towed en route. The company owns two of these trucks and three trailers. The ton-mile expense with

these vehicles has figured out at 15 cents.

Contract haulage offers an exceptional opportunity for the truck to demonstrate its economy and efficiency, but it often is necessary to devise some means for quick loading or unloading. The tractor and trailer method is growing in favor, and a number of manufacturers are specializing in such equipment, either with tractors or trailers. Other makers have brought out specially constructed bodies arranged to be dumped by the power of the motor propelling machine.

As has been stated, no attempt has been made to exhaust the subject. The examples cited merely indicate a few of the many fields in which trucks are constantly being used to advantage. Highway haulage is rapidly assuming a position of decided importance in the business world, and, in its many ramifications, is of such deep practical interest as to merit extended consideration. Our contemporary, Motor Truck, is devoted solely to this branch of the industry, and in each number different phases of commercial vehicle service are treated in a manner calculated to make an appeal to the thoughtful business man.

Foden Steam Truck and Two Trailers in Contract Haulage with Terminal Transport Company, New York City.

IS EASTERN REPRESENTATIVE.**W. S. Jewell Will Cover New England, New York, New Jersey and Pennsylvania.**

The Marion Motor Car Company, Indianapolis, Ind., announces the appointment of W. S. Jewell as eastern sales representative, in charge of the territory embracing New England, New York, New Jersey and Pennsylvania. He is one of the veterans in the trade, and is widely and favorably known throughout the industry. For some few months he has been manager of the New York house handling Marion cars, and his appointment may thus be looked upon as a distinct advance and extension of his duties and powers.

Mr. Jewell became identified with the industry some 12 years ago, when he joined the company formed by Richard Croker and other New Yorkers for launching the first taxicab service in the United States. Previously he had been connected with a series of successes in electric street railway operation. Later he joined the staff of the H. H. Franklin Manufacturing Company, as manager of the New York branch. After three years he became general manager of the Motors Engineering Sales Company, distributor for the Kelly truck in the East. Still later he took over the metropolitan district for the R-C-H Corporation, with headquarters in New York, but directing sales in Philadelphia and Boston as well. His connection with the Marion company dates from last summer.

ALLEGES INFRINGEMENT.**Maker of the Gasolock Brings Patent Suit in United States District Court.**

According to information from Detroit, the Headlight Support Company of that city, maker of the Gasolock, has brought suit in the United States court for that district against the Esco Manufacturing Company, also of Detroit, alleging infringement of patent No. 1,025,105, granted to F. E. Youngs on an application filed July 8, 1908.

It is maintained by the complaining company that the claims of the patent are sufficiently broad to cover every possible type of device which employs a lock for controlling the flow of fuel oil from the fuel tank to the engine. It is also held that this patent has been infringed unwittingly by many users of automobiles, who have permitted locking devices of this type to be

installed on their cars by persons not licensed by the Headlight Support Company, which states that it will protect its patent in the courts against deliberate infringements.

THE RAYFIELD TROPHY.**Punch Bowl and \$1000 in Gold Goes to Winner of This Year's 500-Mile Race.**

Announcement is made by the Findeisen & Kropf Manufacturing Company, Chicago, maker of the Rayfield carburetor, that it will offer a handsome punch bowl, to be known as the Rayfield trophy, to the winner of the fourth annual 500-mile race on the Indianapolis motor speedway, May 30, providing the car is equipped with a carburetor of this make. In addition to the trophy, which is valued at \$2000, and which becomes the permanent possession of the driver winning it twice in a Rayfield equipped machine. \$1000 in gold will go to the driver. The driver finishing second will receive \$300 in gold and the one in third place will receive \$200, under the same provision in each instance.

**Rayfield Carburetor Trophy.**

The Rayfield trophy is a massive punch bowl of solid sterling silver, gold lined and made from an original design. It stands 17 inches high, is 16 inches in diameter and 20 inches wide from handle to handle. Around the top of the bowl is a beautifully arranged border, divided into four parts; two panels forming the front and back, illustrate the speedway and show racing cars going at full speed, all cleverly hand wrought.

The Firestone Tire & Rubber Company, Akron, O., announces that it will market cyclecar tires in four sizes, 28 by 2.5, 28 by 2.75, 28 by three and 29 by 2.75 inches. It is understood that these tires have been subjected to road tests in and about Akron, and other experiments, during the past two years. Red and gray inner tubes also will be produced to fit these sizes.

INCREASE IN SALES.

Electric Storage Battery Company Makes Public Its Annual Statement.

The Electric Storage Battery Company, Philadelphia, Penn., has made public its annual report for 1913, showing gross sale of \$1,558,123, as compared with \$1,536,190 during 1912. The total net income was equal to 6.71 per cent. on the \$18,000,000 capital stock, \$155,000 of which is preferred, as compared with 6.25 per cent. for the previous year. The comparative table follows:

	1913	1912
Gross sales, less cost, mfg., etc.	\$1,558,123	\$1,536,190
Operating expenses	522,205	512,354
Net	\$1,035,917	\$1,023,835
Other income	172,837	101,443
Total net income	\$1,208,755	\$1,125,279
Less dividend	649,964	649,964
Surplus	\$558,797	\$475,315
Previous surplus	2,855,525	3,318,080
Less adj. net	101,793	*937,871
Total surplus	\$3,312,522	\$2,855,525

*Consists of an allowance of \$808,400 for depreciation of United States Motor Company securities, \$48,539 loss in value (undepreciated) of old buildings replaced by new factory, and \$128,741 deducted for sundry adjustments and items not incident to the current year, partially offset by an addition of \$47,619, representing the par value of bonus stock of Chloride Electrical Storage Company, Ltd.

HIGH SCHOOL COURSE.

Plans Under Way Looking Toward Addition of Automobile to the Curriculum.

Plans are being formulated by George D. Strayer and Thomas H. Briggs, professors of the education department of the Teachers' College, Columbia University, looking toward the introduction of the study of automobiles in the high schools of the United States as a subject just as important as any other for the student to take up. This became known recently as the result of a visit by these two men to the University of Indiana, at Bloomington, Ind., where Prof. R. F. Myers of the high school division of that institution, has been using the Cole Technical Bulletin and a Cole car in teaching the subject of physics.

Prof. Myers contends that to the average high school pupil's mind an automobile has been something that runs and gives pleasure. But what makes it run, the functions of the various parts of machinery, gas expansion, its electrical appliances, etc., have been a mystery. As a mat-

ter of fact, it should not be, he declares, because the most important principles of physics can be clearly defined in the motor car.

It appears, however, that Prof. Myers is not the only instructor to utilize the Cole treatise, which was prepared by Chief Engineer Charles S. Crawford of the Cole Motor Car Company, Indianapolis, Ind., in this manner. Other schools in the United States which are conducting similar classes are: Engineering department, University of Michigan, Ann Arbor, Mich.; department of mechanical arts, University of Arkansas, Fayetteville, Ark.; department of journalism, New York University, New York City; department of industrial arts, Mechanics Institute, Rochester, N. Y.; and the high schools in Terre Haute, Evansville, Marion, Shelbyville, Rochester, Logansport, Kokomo, Petroleum, Mishawaka, Wabash and Gary, Ind.

NEW BRANCH MANAGER.

Stewart-Warner Speedometer Corporation Announces Changes in Two Cities.

Frank M. White, who was formerly manager of the Stewart-Warner Speedometer Corporation's New York branch, and who for the last two years has been at the company's factories in Chicago, has returned to his former position in New York City, while F. O. Fleischer remains as office manager.

J. J. Hildebrecht, who has been manager of the Pittsburg branch, has taken up his new duties as special salesman for the company. His place has been filled by the appointment of A. T. Henderson.

MERCER MOTOR ON WATER.

Cincinnati Man Buys One for Installation in His Power Boat America.

In view of the record breaking performances of Mercer cars, made by the Mercer Automobile Company, Trenton, N. J., on tracks and highways, it is interesting to note that Mercer speed is no longer to be confined to land. Perhaps a Mercer motor may be utilized even for flying one of these days, but it is sufficient for the purposes of this item to state that one has been installed in the power boat America.

The owner of this boat is Max C. Fleischman of Cincinnati, O. He recently purchased the motor and shipped it to Jacksonville, Fla., where it was fitted to the America. On its first trial run it showed a speed of 58 miles an hour.

SMALL PARCEL DELIVERY VEHICLES.

A Somewhat New Branch of the Industry, in Which the Needs of Merchants and Others for a Light, Fast Means of Making Deliveries Are Given Consideration.

EVEN the butcher, the baker and the candlestick maker—if the last named individual is still doing business, and, if not, his present day counterpart—may find exactly the type of vehicle adapted to their needs. This should not be taken to mean that the offerings of the automobile industry in this particular field are limited in any manner to the specific lines mentioned. There are many concerns which find use for a small parcel delivery car, and it is to these that the type of vehicle under consideration is expected to make a direct appeal.

Back in the early days of the industry's history—about 1903, if memory serves correctly—the Knox Automobile Company of Springfield, Mass., produced what has ever since been regarded as the first parcel delivery car. This was to specifications supplied by Smith & Murray, a large department store in that city, which desired a rapid means of delivering small packages about the city and suburbs. This equipment proved to be a decided success from a practical viewpoint, and other machines of a similar character were produced by this manufacturer and others. However, it is within a comparatively short time that the industry has given this type special consideration.

The demand has existed, and in many instances it has been supplied by the motorcycle manufacturer with the delivery van, either in front or at the side of the motorcycle proper. This combination has its distinct field of usefulness, and it hardly will be contended that other types of vehicles will entirely supplant it, but particular attention is drawn at this time to a number of new machines which have made their appearance more recently.

These virtually may be divided into three classes, although there is the same tendency to-

ward confusion that exists in an attempt to classify passenger vehicles, in that one of these classes must be designated as a cyclecar. A second might be termed—indeed, it is termed by some makers—a motorcycle truck, while the third is a miniature delivery wagon. Some of the last named have three wheels and others four. It readily will be seen that it is a difficult matter to classify these machines in a manner satisfactory to all concerned. All are designed primarily as parcel delivery wagons.

Motorcycle Trucks.

Typical examples of the so-called motorcycle truck are the products of the Harley-Davidson Motor Company, Milwaukee, Wis., and the Minneapolis Motor Company and Shapiro-Michael-

Latest Type of Motorcycle Package Carrier Is Represented by Harley-Davidson.

son Motor Company of Minneapolis, Minn. Each of these comprises the regulation motorcycle frame, insofar as the rear wheel, saddle and motor support are concerned, but the front forks are replaced by stronger supports which connect with a chassis frame carrying a delivery van between two wheels at the front, and with side frame members extending backward to the rear wheel hub. This type of construction is brought out very clearly in the illustration of the Harley-Davidson shown herewith.

It will be seen that this design is a direct outgrowth of the motorcycle, although the construction is with an idea of permitting much larger loads to be transported than with the motorcy-

The Packet Cyclecar Delivery Wagon Model Made in Detroit.

cle and van attachment. The Michaelson is rated at 300 pounds capacity, the Minneapolis at 500 and the Harley-Davidson at 600. In general design they are very much alike, but the details have been worked out differently, as might be expected. The Michaelson and Minneapolis are fitted with single-cylinder engines, and the Harley-Davidson with a twin.

Cyclecar Delivery Wagons.

Since the advent of the American cyclecar, a number of the manufacturers engaged in the production of these machines have announced delivery car models. It must be remembered that the cyclecar situation at present is that of a new business which is not actually established. By this is meant that the product is still in an experimental stage, and, even with those manufacturers who are prepared to produce machines, there is as yet some little indecision as to exact features of design and construction. It is probable that other concerns will announce delivery car models as soon as they are in a position to make definite arrangements concerning their product.

It is by no means certain that the following list of cyclecar delivery wagons includes all which have been announced, but they will serve to indicate the features of the type: Imp, Imp Cyclecar Company, Auburn, Ind.; Comet, Comet Cyclecar Company, Indianapolis, Ind.; La Vigne, La Vigne Cyclecar Company, Detroit; Packet, Scripps-Booth Cyclecar Company, Detroit; Merz, Merz Cyclecar Company, Indianapolis; A. C., Autocycle Company, New Orleans, La., and Twombly, Twombly Car Corporation, New York City. All of these are made with the package com-

partment at the rear, instead of at the front as with the so-called motorcycle trucks.

The Imp, Comet, Merz and Packet are true cyclecars, under the definition of the Cyclecar Manufacturers National Association. That is, they have motors with piston displacement of less than 71 cubic inches. The A. C., La Vigne and Twombly are light cars, under the same definition, these having motors with piston displacement of larger capacity. As a matter of

fact, these definitions really apply to the pleasure car models, but it is assumed that they will be made to apply to the delivery cars as well.

Some Constructional Details.

The Imp uses a two-cylinder engine, with bore of 3.375 inches and stroke of 3.875; friction transmission and V belt drive, and is rated at 300 pounds capacity. The Comet has the same rated capacity, and is fitted with a two-cylinder engine, with bore of 3.5 inches and stroke of 3.675; expanding ring clutch, planetary transmission and V belt drive. The Merz has a motor of the same size and type as the Comet, friction transmission and V belt drive. Its capacity is placed at 500 pounds. The Packet has a two-cylinder engine, with 3.5-inch bore and 3.66-inch stroke; disc clutch, planetary transmission and V belt drive. The rated capacity is 350 pounds. With all of these the motors are air-cooled.

Of the light cars mentioned: The La Vigne has a four-cylinder, water-cooled motor, with bore of 2.375 inches and stroke of four; multiple disc clutch, sliding gear transmission, and drives by shaft and worm gear. Its capacity is 400 pounds. The A. C. also has a four-cylinder, water-cooled motor, the dimensions of which have

The Merz Cyclecar Delivery Wagon Produced in Indianapolis.

not been made public. Drive is by shaft, and the capacity is not stated. The Twombly motor has four cylinders and is rated at 15 horsepower. Cooling is by water, thermo-syphon system. A friction transmission, single-chain drive and two-speed rear axle are employed. The carrying capacity is 500 pounds.

Specially Designed Wagons.

The vehicles which have been mentioned must be regarded as practical in every way, but they are distinguished from those of the third class, in that, while they are specially designed insofar as their application to the work for which they are intended is concerned, they are more or less closely identified with passenger machines. The motorcycle truck is a motorcycle redesigned for a specific commercial service, and the same thing may be held to be true, at least in a measure, with respect to the cyclecar delivery wagon. The third class is held to be designed throughout for business purposes.

It may be stated in this connection that it is not considered essential that a machine shall be specially designed, throughout, in order to be enduring in the light, fast work for which such cars are usually employed. It depends very largely upon the class of service in which it is intended to utilize the car. There are lines in which it undoubtedly would prove most advisable to have a machine more sturdily constructed, and it is for such work that the vehicles in this third class are primarily intended, although, of course, they are equally capable of supplying the service for which the other two types are particularly adaptable.

Light Commercial Car.

One of these machines is the Light commercial car, made by the Light Commercial Car Company, New York City. In some respects this machine resembles a motorcycle truck and in others a cyclecar delivery wagon. For instance, it is equipped with handlebars instead of the regulation steering wheel, and it has a two-cylinder, air-cooled motor rated at nine horsepower, which is located directly in front of the rear wheel and beneath the seat. It should be understood that the Light is a three-wheel vehicle, all three wheels being of wire and fitted with 26 by three-inch heavy tread tires. The wheelbase is 66 inches and the tread 46. The van is located in front, and is rated at 600 to 800 pounds carrying capacity.

The motor is supplied from a 2.5-gallon gasoline tank at the back of the seat. Ignition is by high-extension magneto or battery. Drive is by roller friction or standard chain as desired, and

the speeds are said to be from two to 35 miles an hour on the high and 10 miles an hour on the low, both being direct. An external contracting brake, 10 inches in diameter and one-inch in width, is applied to the rear wheel hub, this being actuated by pedal. Springs are semi-elliptic. The throttle control is by grip on the right handlebar, and spark control at the centre and just below the handlebars. The speed control is by two pedals.

Wagenhals Tricar.

The Wagenhals is another three-wheel machine, made by the Wagenhals Motor Company, Detroit, although this differs materially from the machine just described. Instead of being located under the seat, the motor is under a hood midway of the chassis, just behind the van. This is a water-cooled, four-cylinder unit, with bore of 3.5 inches and stroke of 3.375, cast in parts. This

The Wagenhals, a Three-Wheel Package Car.

drives through a cone clutch and planetary transmission, final drive to the rear wheel being by chain. Control is by pedal in the centre. The springs are semi-elliptic. The wheelbase is 80 inches, and the van in front has capacity of 800 pounds. Wheels are of wood, fitted with 30 by three-inch tires in front and 34 by 4.5 inches in the rear.

Parcel Post Kar.

The Parcel Post Kar is the product of the Parcel Post Equipment Company, Grand Rapids, Mich., and is a four-wheel machine with carrying capacity of 500 pounds. The van is located in front, and the motor is between it and the seat. The van portion is made detachable, and may be lifted off with ease, exposing the engine for work or adjustment.

The motor is a two-cylinder, air-cooled V type, with bore of 3.5 inches and stroke of 3.5625.

Ignition is by Bosch high-tension magneto, and carburetion by a Schebler. The clutch is a multiple disc and the sliding gear transmission affords three forward speeds and reverse. Final drive is by chain, running in oil. Brakes are external, inside the rear axle housing, and are fitted with cork inserts. The springs are semi-elliptic in front and full elliptic in the rear. The wheels are of wire, fitted with 30 by 3.25-inch tires.

The MotoKart.

The MotoKart is made by the MotoKart Company, formerly the Tarrytown Motor Car Company, with offices at 1790 Broadway, New York City, and factory in Tarrytown, N. Y. This is a specially designed machine which differs from the others, in that the motor is located under the seat, which is over the rear axle, and the chassis is mounted on four wheels. The van is in front,

axle by single chain. The frame is of pressed steel channel section, mounted on semi-elliptic springs, the driving thrust from the rear axle being taken by radius rods. Wheels are of wire, fitted with 26 by 2.5-inch tires, of the non-skid motorcycle type.

Control is by a vertical steering column and hand wheel located in the centre of the floor-board, and by an accelerator and pedal that actuates the driven disc. A hand lever at the right operates the driven wheel on the jackshaft. The brake is actuated by another pedal. The chassis is fitted with running boards and fenders, and a tool box is carried on the left running board.

From the examples cited, it will be noted that it is possible for the merchant or other establishment to secure a machine which will best meet individual needs. The list has by no means been exhausted. In fact, new machines of

one type or another suggested herein, are being announced very rapidly, particularly in the cycle-car field. All of those mentioned are listed at a moderate price; at a figure which compares very favorably with that which would be paid for a horse and wagon, in the open market. And when consideration is given to the range of movement, speed and cost of upkeep

The Motokart, a Specially Designed Parcel Car, with Motor Located at the Rear.

and has a normal capacity of 400 pounds. A feature of the equipment emphasized by the maker, is that its size and weight are such that it may be housed in the store after business hours. The wheelbase is 69 inches and the tread 44. The dimensions of the van are: Length 51 inches, width 32 and height 32. The overall length of the machine is 106 inches, the overall width 52 and the extreme height 52. The weight is approximately 700 pounds.

The motor is a two-cylinder, four-cycle unit, with bore of 3.63 inches and stroke of four, this being rated by the maker at 10-12 horsepower. The cylinders are cast singly. Cooling is by water, thermo-syphon system, through a large honeycomb radiator. A friction transmission affords an unlimited range of speeds, and power is transmitted from the jackshaft to the live rear

axle by single chain. The frame is of pressed steel channel section, mounted on semi-elliptic springs, the driving thrust from the rear axle being taken by radius rods. Wheels are of wire, fitted with 26 by 2.5-inch tires, of the non-skid motorcycle type.

Correction of Error—In the March 10 issue in New Accessories for the Motorist an illustration of the Mosco Ford wheel puller was utilized in a description of the Mosco anti-rattling ball socket. This was an error. A description of the Mosco Ford wheel puller will appear in the April 10 issue of The Automobile Journal.

The Galveston Electric Company, Galveston, Tex., reports a Studebaker automobile, made by the Studebaker Corporation, Detroit, which has been in continuous service for four years and has acquired a definite record of over 200,000 miles.

GENERAL NEWS OF THE INDUSTRY.

Kissel Company Gives Up Philadelphia Branch--Chalmers Concern to Take Over New York Agency--Page Joins Owen in Handling Entz Transmission.

THAT there is still some little difference of opinion among automobile manufacturers as to the advisability of maintaining branch houses for the distribution of cars, is borne out by the activities of the past two weeks. Following the plan adopted in Chicago, the Kissel Motor Car Company, Hartford, Wis., has abandoned its KisselKar branch in Philadelphia, the business being transferred to the Gibbons-Wetherill Company, which already handled the Maxwell line. This concern recently leased the three-story building vacated by the Alco Company, and as a result has one of the best equipped service stations for pleasure cars and trucks in the city.

Practically coincident with this announcement comes the information that the Chalmers Motor Company, Detroit, is to take over the business heretofore conducted in New York City by the Carl H. Page Company, as agent for Chalmers cars, and the plant will be operated in the future as a Chalmers branch. It should be stated, however, that this information has not as yet received public confirmation, those interested declining to confirm or deny the report. It is impossible to suggest whether or not the deal will include the other Page companies in several Connecticut cities.

It is understood that Mr. Page, who has been connected with the industry in New York City for many years, is to withdraw from the sale of Chalmers cars entirely, combining his interests with those of R. M. Owen, who recently gave up the distribution of Reo cars, in the promotion of the Entz electric transmission.

NEW STUTZ PLANT.

Additional Details Concerning Factory of Well Known Indianapolis Concern.

As stated in the last issue of The Automobile Journal, the Stutz Motor Car Company, Indianapolis, Ind., has begun work on its new plant at

10th street and Capitol avenue, on property recently purchased from Harry S. New. It will adjoin the factory occupied by the former Stutz Auto Parts Company, which is now a part of this concern. An accompanying illustration indicates the character of structure which it is proposed to erect.

The new building will be one of the most up-to-date automobile plants in Indianapolis. It will have a frontage of 80 feet on Capitol avenue and 204 feet on 10th street, and will be four stories in height. The material will be concrete with brick facings, and steel frame windows will furnish an ample supply of light.

The general offices and the assembly plant, which are now located at 430 North Capitol avenue, will occupy the first floor. The offices will

New Plant Which Stutz Motor Car Company Will Erect in Indianapolis, Ind.

be on Capitol avenue, and back of these will be a storage room for such heavy parts as frames, motors, transmissions and axles. The second floor will contain the first and final assemblies, and the third floor will house the paint shop and finishing department. The fourth floor will be used as a top building and upholstery shop.

Porte-cocheres will be erected at both the Capitol avenue and 10th street entrances, and a big sign, displaying the unique Stutz trade mark, and bearing the slogan, "The car that made good in a day", will be built into the top part of the centre of the structure. It is estimated that the new factory will cost over \$100,000. It will be used entirely for manufacturing purposes, the city salesroom being retained in its present location.

ANNOUNCES NEW OFFICERS.

Men Named to Head MotoKart Company, Which Takes Over Two Older Concerns.

As announced recently, the MotoKart Company has been incorporated under the laws of New Jersey to take over the business heretofore conducted by the Tarrytown Motor Car Company, maker of the MotoKart light delivery wagon, and the Steinbock Engineering Company, which supplied the parts for this machine. The offices of the company will be retained at 1790 Broadway, New York City, and the factories at Tarrytown and Peekskill, N. Y., have been transferred to the new concern. As a result of the consolidation, new officers are announced as follows:

A. R. Gormully, President, MotoKart Company.

President, A. R. Gormully; vice president, H. E. Steinbock; sales vice president, G. C. Wolfe; treasurer, B. J. Knerr; secretary, E. M. More; purchasing agent, F. C. Sievers.

President Gormully is well known in the industry. He was born and educated in London, England, and came to Boston in May, 1892. He began active business life with the Gormully & Jeffery Manufacturing Company, Chicago, as an office boy, and arose to become manager of the export department before leaving this concern in 1900. The next two years were spent with the Electric Vehicle Company in its first plant in New York City, as superintendent's assistant. From 1902 to 1904 he was assistant manager of the Erie Basin Works, maker of general machinery, and in 1905 he went with the Vehicle Equipment Company, Long Island City, as purchasing agent. After that he was for four years purchasing agent for the Maxwell-Briscoe Motor Company, Tarrytown, N. Y., and upon the formation of the United States Motor Company he held the position of general purchasing agent

until he resigned in December, 1912, to become treasurer of the Steinbock company.

JOINS OAKLAND FORCE.

Fred W. Warner Becomes General Sales Manager, Vice J. B. Eccleston, Resigned.

Announcement is made by the Oakland Motor Car Company, Pontiac, Mich., of the appointment of Fred W. Warner as general sales manager, succeeding J. B. Eccleston, who has resigned. Mr. Warner was originally connected with the wholesale implement business, but for the past three years has been manager of the Buick Motor Company's Chicago branch.

In 1890 he joined the selling force of the John Deere Plow Company at Kansas City, as travelling salesman, and was with that concern for 14 years in various positions, being sales manager during the last four years, in Colorado, Oklahoma, New Mexico and Arizona. When he left that company in 1904 he opened and managed most successfully a branch house at Dallas, Tex., for the Racine-Sattley Company. Six years ago he became associated with the Keating Implement & Machine Company, the oldest house of its line in the Southwest, as secretary and sales manager.

ON HIS WEDDING TRIP.

A. H. Bartsch Also Found Time to Establish a Score of Bosch Service Stations.

It appears, according to information from New York City, that Alfred H. Bartsch, advertising manager for the Bosch Magneto Company, was married Feb. 10, leaving that night with his bride for Los Angeles, Cal., to witness the Vanderbilt Cup and Grand Prize races. On the way he stopped at the Grand Canon in Arizona, and was somewhat disappointed to find that only horses and burros were used in that vicinity, so that he was unable to establish a Bosch service station.

However, he joined Chief Engineer V. W. Kleisrath in Los Angeles and together they saw to it that those interested had the usual good Bosch service. On the return trip, Mr. Bartsch visited the western distributors, stopping off in San Francisco, Sacramento, Salt Lake City, Denver and Chicago. While in San Francisco he arranged the details for the Bosch exhibit at the Panama-Pacific exposition in 1915. He also established over 20 new Bosch service stations west of Chicago.

TAKES OVER VULCAN GEARSHIFT.**Cutler-Hammer Manufacturing Company Will Continue Its Production in Milwaukee.**

Announcement is made by the Cutler-Hammer Company, Milwaukee, Wis., well known as the maker of electric controlling devices, with branches in New York, Boston, Philadelphia, Pittsburg, Cleveland, Cincinnati, Chicago and San Francisco, that it has taken over the production and marketing of the Vulcan electric gearshift. This has been made heretofore by the Vulcan Motor Devices Company, Philadelphia, and is standard equipment on the Haynes, Pullman and other cars for 1914.

Roger W. Griswold, president of the Vulcan Motor Devices Company, and W. A. McCarrell, chief engineer, will continue to be actively interested in the manufacture of the product. A new department of the Cutler-Hammer Company, to be known as the Vulcan electric gearshift department, has been created to handle this business, with headquarters in Milwaukee.

REJOINS MERCER FORCES.**Designer of Deltal Special Racing Car Becomes Company's Chief Engineer.**

E. H. Delling has been appointed chief engineer and designer of the Mercer Automobile Company, Trenton, N. J., maker of the Mercer line, succeeding Finley R. Porter, resigned. He is not exactly a new man in the Mercer ranks, since he was connected with the concern in the capacity of assistant engineer about two years ago.

Mr. Delling is well versed in European engineering practise, and his ability as a designer of high speed, high efficiency motors is somewhat well known in the industry. He built the Deltal car, a special racing machine, which finished in second place in the contest for the Chicago Automobile Club's trophy at Elgin, Ill., last August. He also had a share in designing the Mercer car which made such a wonderful showing in the 1912 and 1913 500-mile races on the Indianapolis motor speedway.

In connection with the resignation of Mr. Porter, it is stated that he has secured temporary offices at 1790 Broadway, New York City, until complete arrangements for factory location and organization can be made, at which time he expects to announce an entirely new car, to be produced in two four-cylinder models. Mr. Por-

ter went with the Mercer company as chief engineer four years ago and one year later became factory manager as well. His experience in the industry should place him in an exceptional position to undertake the production of a car of his own.

WATERMAN SUCCEEDS REEVES.**Resumes Active Connection with Hartford Suspension Company After Year's Lapse.**

It will prove of interest to the many friends of Arthur Waterman, both in and out of the industry, to learn that he has returned to the Hartford Suspension Company, Jersey City, N. J., as vice president and general manager, succeeding Alfred Reeves, who resigned to become general manager of the National Automobile Chamber of Commerce. Mr. Waterman was formerly sales and advertising manager of this company, until shortly before the New York show of 1913, at which time Mr. Reeves became identified therewith.

Arthur Waterman, Vice President, Hartford Suspension Company.

In the interim, Mr. Waterman has been connected with the G. C. Vaporizer Company of America, New York City, as sales manager. He is well acquainted with the products of the Hartford Suspension Company and is thoroughly conversant with the methods employed in marketing them.

TO REVIVE AMPLEX CARS.**Company Organized to Produce Machines Equipped with Sleeve Valve Motor.**

According to information from Mishawaka, Ind., operation of the plant of the Amplex Motor Car Company will be continued by a new con-

cern, recently organized by Chicago men, under the name of the Amplex Manufacturing Company, with capital of \$500,000. These men include W. R. Randall, H. M. Pulcifer, W. Mackerstaff and H. Paulin.

It is understood that it is the plan of the new concern to produce a six-cylinder car, equipped with a new type of sleeve valve motor, designed by E. J. Gulick.

NOW GENERAL SALES MANAGER.

R. J. Schmunk Succeeds to This Title After Seven Years with Peerless Company.

Announcement is made by the Peerless Motor Car Company, Cleveland, O., maker of Peerless

R. J. Schmunk, General Sales Manager, Peerless Motor Car Company.

cars and trucks, that R. J. Schmunk, who joined the selling force of that concern about seven years ago, has been made general sales manager, the chief executive of the selling division. Shortly after his connection with the company he was made sales manager, and a year ago his title was changed to director of sales,

with largely increased duties and responsibilities. This latest appointment places upon him the entire management of the marketing of the Peerless product.

Mr. Schmunk has been connected with the motor car industry from its very inception, and knows its history in all its ramifications. He has served in a wide variety of capacities with several well known companies, and in different parts of the United States. He has made the acquaintance of thousands of dealers from the Atlantic to the Pacific, and from Canada to Mexico, all of whom will be glad to congratulate him upon assuming his new responsibilities.

Another promotion in the Peerless ranks announced recently is that which resulted from the

election of T. C. Frech as director, in place of F. S. Terry, and vice president, succeeding J. B. Crouse. He also becomes general manager of the company.

STUDEBAKER'S ANNUAL REPORT.

Gross Business of \$41,464,949.82 and Net Profits of \$1,772,473.65.

The annual report of the Studebaker Corporation, Detroit, shows a gross business for the calendar year of \$41,464,949.82, as compared with \$35,440,327.41 during the previous year. This is an increase of 17 per cent., and is the largest volume of business in the history of the company. The net profits from all sources, after payment of interest, etc., were \$1,772,473.65.

Concentration on two models, a four and a six, during the latter part of the year proved a stimulus to trade, and prospects for 1914 are indicated in the figures for January and February, 1914, which show the following: Cars produced, 5703 in 1914, as against 2581 in 1913, a gain of 121 per cent.; cars sold for cash, 5720 in 1914 as against 3019 in 1913, a gain of 89 per cent.; cash receipts, \$4,827,812.95 in 1914, as against \$3,385,948.94 in 1913, a gain of 43 per cent.

SINGER'S NEW CAR.

Temporary Headquarters in New York City and Factory on Long Island.

Supplementing the information made public coincident with the recent appointment of a receiver for the Palmer & Singer Manufacturing Company, incorporation papers for Singer Motor Company have been filed at Albany, N. Y. The authorized capital is \$200,000 and the incorporators are: Charles A. Singer, formerly president of the Palmer & Singer Manufacturing Company; C. A. Singer, Jr., and Harold Callisen. Temporary headquarters have been established at room 707, Longacre building, New York City, and a factory has been secured on Long Island.

A. M. Dean, formerly consulting engineer for the Palmer & Singer Manufacturing Company, and the Matheson Automobile Company, has been retained in a similar capacity with the new concern. It is understood that the new car will be a six-cylinder machine, constructed along the same lines as the Palmer-Singer. It is stated this new car will utilize a T head poppet valve motor, with four-inch bore and stroke of 5.5.

NEW ACCESSORIES FOR THE MOTORIST.

A. A. A. SPECIALTIES.

Include Headlight Rod, License Plate Holder and Brake Handle.

The A. Auto Appliance Company, 114 West Exchange street, Providence, R. I., is manufacturing three

new specialties for the model T Ford car. The one shown in the upper part of the illustration is an emergency brake pawl release handle, which is held to eliminate all vibration and noise and to improve the operation of the lever. The handle is one inch longer than the conventional member and is designed to fit the palm of the hand. It is made of high grade malleable iron and the release pawl is fitted with a heavy piano wire coil spring.

The device shown at the bottom of the illustration is an adjustable headlight rod, which prevents rattling of the lamps, and is also provided with a license number plate bracket. The holder is made of heavy brass tubing with bronze ends. The centre illustration depicts the A. A. A. number plate bracket.

FISHER MOTOR-GENERATOR.

Lighting and Motor Starting System for Model T Ford Cars.

The Fisher Electrical Works, 1690 Larned street, West, Detroit, maker of electric lighting and motor starting systems, is manufacturing an equipment designed for service with the model T Ford automobile. It is a unit system, a motor-generator, and one of the qualities of the design is that it may be installed without machine work or drilling. It is a 12-volt, three-wire system, and six-volt lamps are employed.

The complete equipment comprises a silent chain, two sprockets, pulley for fan belt, zero line ammeter, starting and lighting switch, cables, adjustable supporting bracket, 12-volt 35 ampere-hour capacity storage battery and the motor-generator.

The unit is mounted on the left hand side of the motor, a special bracket being bolted to the power plant. Drive is by chain, a sprocket being fitted to the crankshaft. When current is led to the unit from the battery, it functions as a motor, rotating the crankshaft by means of the silent chain. Upon the motor starting, the current being cut out from the battery, the unit functions as a dynamo, charging the cells.

STANDARD AUTO-THERMO.

Indicates Temperature of Motor by That of Cooling Fluid.

The Standard Thermometer Company, 65 Shirley street, Boston, is marketing the Standard auto-thermo, which is a neat, compact device fitted to the radiator cap and is adapted for attachment to either the hinged or screw cap. It is fitted by boring a hole in the cap, inserting the extension and tightening a nut on the last named member. The part extending

into the radiator actuates a hand which moves over a calibrated dial, the degree and direction of movement being influenced by the temperature of the fluid of the cooler, or, in other words, the motor.

The hand moves across transparent zones, and temperatures equalling that of freezing, maximum motor efficiency and steaming are shown. When the hand is in a vertical position, it indicates "Safe"; that is, the cooling water is at a temperature when the motor is operating at its maximum efficiency insofar as temperature is concerned. The Standard auto-thermo is finished in nickel, brass or black enamel and is moderately priced.

Ed. Note.—The editor of this department wishes to acknowledge the receipt of a number of new accessories from manufacturers. Some of these are presented in this issue, while others were received too late for publication, but will be described and illustrated in the April 10 issue of The Automobile Journal. Several descriptions of devices have been received without illustrations, which should be forwarded to insure their publication.

UNIVERSAL TAIL LIGHT.

Electric Lamp, Solderless and Made in Two Styles.

The Combination Tail Light Company, 954 Tremont street, Boston, is manufacturing an attractive, compact

electric tail light termed the Universal. It is fitted with an ingenious device which throws a soft, strong light over the entire surface of the number plate, and the maker lays emphasis on this point, stating that glaring is eliminated, and that the illumination conforms with the laws. The lighting device is attachable or detachable instantly, overcoming troubles in replacing a damaged bulb with a new one. Any bulb with an Edison base and not more than 1.25 inches in diameter may be used.

One of the features of the design is the use of a combination socket, which will fit the bracket of any car. Soldering has been eliminated in the Universal, all parts being electrically welded, making for durability. It is made in two styles, C, having a steel back, nickel and enamel top and finished in nickel and black outside.

AUTO PARTS RADIATOR.

V Shaped Honeycomb Design for Model T Ford Cars.

The Auto Parts Company, Chicago, is marketing a special design of radiator for the model T Ford automobile. It is of the V shaped design, and is stated to be a genuine honeycomb type. It is constructed to replace the regular cooler and without any alteration or special fittings. It is made with two finishes, nickel plate and brass, the latter listing \$2 less.

The company is also marketing the P. G. N. headlight, which provides three lighting equipments in one. The upper section of the lamp forms the usual acetylene headlight and the lower an electric unit. Between them, at the right and left, are two small electric bulbs for city driving.

GEMCO SPARK PLUG PUMP.

Constructed Especially for the Model T Ford.

The Garage Equipment Manufacturing Company, Milwaukee, Wis., has brought out a special power

pump for the model T Ford car, and those of similar size, termed the Gemco. It is screwed into the spark plug opening in the cylinder and is actuated by the compression of the motor. The cylinder of the pump is provided with a piston and rings, and these are machined and fitted carefully to insure maximum efficiency.

The principle of the pump is that of an air compressor and it is stated that only pure, fresh air is pumped to the tires. The pump comes packed in a neat box with 12 feet of rubber hose, necessary connections and adapters for attaching to any motor. A gauge for indicating the pressure is listed at slightly extra. The Gemco is finished in what is termed hard rubber black enamel.

CROWN PRINCE WHEELS.

Demountable Design Constructed of Pressed Steel.

The use of pressed steel in motor car construction is becoming more general and a new application of the material, at least in this country, is noted in the Crown Prince pressed steel wheels, which are being marketed by Max Bacham, 845 Jefferson avenue, East, Detroit.

It is held that they are 200 per cent. stronger than wooden members, lighter, and considerably more durable. It is also claimed that much more tire mileage is obtained and that greater speed is possible. One of the qualities of the design emphasized is that it will not collapse; merely bend when subjected to severe stresses which would break wooden constructions. Being of metal the Crown Prince design cannot shrink or the spokes become loose.

The Crown Prince is a demount-

able wheel, and it is stated that it may be removed and an extra member is fitted in about one minute. It is retained by five nuts, which are displaced by a brace type of wrench. The wheels are equipped with either clincher or quick detachable rims and it is stated that they weigh only a few pounds more than the average demountable rim.

PASCO ELECTRIC SIDE LIGHT.

Design Adapted to All Types of Cars and of Special Material.

The Portland Auto Specialty Company, 604 Fidelity building, Portland, Me., is marketing the Pasco electric side lamp, which is a very neat and compact design, intended for cars not equipped with electric lighting, although it is serviceable with any machine. It is designed to provide a large amount of light, a well designed parabolic reflector being employed.

The bulb is placed in a vertical position, a location making for maximum illumination. One of the qualities of the design is that the wiring is concealed, it being carried through the bracket, thence to the

switch on the dash, etc. The lamps are constructed of a special combination silver metal, with polished nickel finished interiors and silver, brass or black enamel outside. They are moderately priced and the complete equipment includes two lamps, bulbs, wire and switch.

DEMOUNTABLE RIMS.

The convenience of demountable rims is appreciated by motorists and their popularity has led several manufacturers to make a specialty of designs for the machine not equipped with these members. It is now possible for the owner of a car equipped with clincher rims to fit the demountable form at a reasonable cost.

A popular priced car that is being given attention by the rim maker is the model T Ford, and several types of quick detachable or demountable rims are being offered at a reasonable cost. Usually the equipment provides for utilizing the same size tires all around, although an exception is noted in one make, which makes possible the use of shoes with which the car comes equipped.

INLAND HAND PUMP.

Compact Design for Attachment to the Running Board.

The Inland hand pump is manufactured by the Inland Manufacturing Company, Chicago, and one of the

features of the design is its compactness. It is but 15 inches when folded; is designed to be attached to the running board by a wing nut arrangement, and is operated by a lever, which also folds.

The cylinder and base are constructed of brass, the former having a bore of three inches and a stroke of 5.625. The piston is of cold rolled metal and is equipped with a leather packing. One of the qualities of the design emphasized is that it will not heat in service, a draught of air flowing through the cylinder at each compression stroke, it is stated. The pump comes complete with eight feet of high grade hose and a pressure gauge.

AUTO FENDER SAFETY LAMP.

Shows a Double Green Light, Indicating Car's Position.

The Auto Fender Safety Lamp Company, Inc., Corinth, N. Y., is manufacturing the Auto fender safety lamp, the utilization of which differs from conventional practise in motor car lighting. The lamp, which is an electrical unit, is placed on the left front fender, throws a double light, showing green to the front and rear, distinctly outlining the fender. This shows the position of the car to the driver approaching in the opposite direction.

The maker points out that the Auto fender safety lamp makes for safety in that it will show the driver of another car the position of the machine fitted with the device, and that the light may be distinguished easily for a considerable distance. One of the qualities of the light is that it has no glaring or dazzling effects even at close range. It is moderately priced; consumes but little current, and may be connected with the regular lighting system.

MABEY COMBINATION LAMP.

Comprises Searchlight and Inspection Features.

Mabey's Electric & Manufacturing Company, 940 North Pennsylvania street, Indianapolis, maker of elec-

trical specialties, is introducing a combination trouble and spot light, as it is called, which presents practical features. The device is shown ready for service as a trouble lamp in the accompanying illustration.

It is a very compact unit, and, as will be noted, is shaped similar to a cigar. The bulb is protected from damage, when using the lamp as an inspection member, by a wire cage, and when not in service is prevented from being broken by a telescopic joint. The last named member provides the spot light feature referred to, and the maker states that a brilliant light is obtained. The device is finished in nickel and has a hard wood handle, 10 feet of cord, Edison socket and an attachment plug.

KRAMER GOVERNOR.

Automatically Controls Speed of the Gasoline Motor.

The B. G. Kramer Company, Milwaukee, Wis., is manufacturing the Kramer governor, which is especially for commercial vehicles, where it is desired to limit their speed to a predetermined number of miles an hour. The device is also applicable to pleasure cars. The instrument is designed to control and maintain a constant speed of an internal combustion engine by governing the velocity of the incoming gases.

It comprises a throttle, connected to a disc member, that is allowed to float under a constant spring tension in a tapered conduit, the tension of the spring determining the maximum motor speed. Upon the velocity of the incoming gases changing, due to variation in engine speed, the position of the disc in the conduit is affected. This results in altering the position of the throttle, allowing more or less mixture, as the case may be, to be fed to the cylinders, and as

the condition may require.

An auxiliary control lever is provided, permitting the driver to obtain any variation of speed up to the maximum afforded by the governor. It is pointed out that not only does the device make for efficiency and economy of fuel, but it cannot be tampered with.

R. O. C. SUPERHEATER.

Raises Temperature of Fuel Before It Reaches Carburetor.

The National Economic Supply Company, 1777 Broadway, New York City, is marketing the R. O. C. Superheater, a device designed to raise the temperature of the fuel before it reaches the carburetor, and consequently, while it is in a liquid state. It is sprayed into the mixing chamber of the carburetor in the conventional manner but, as the gasoline is heated, it is obvious that it vaporizes readily.

The heat of the exhaust gases is utilized to raise the temperature of the fuel, the Superheater being connected in a branch line of the exhaust. The device is installed in the fuel line, consequently all gasoline passes through it before reaching the carburetor.

The advantages claimed for the

Superheater are: Rapid vaporization of the fuel, a more homogeneous mixture in that precipitation is prevented, economy and less carbon. It is pointed out by the maker that low grades of motor fuel may be successfully used without carbonization. The R. O. C. Superheater is very compact, constructed of high grade material and is moderately priced.

LOCKING THE CAR.

It would appear that automobile thieves are growing bolder, judging from the large number of cars reported stolen. This has been responsible for a number of locking devices, which are designed to prevent use of the machine by others than intended. The more inexpensive types lock the car's mechanism so that it cannot be moved, which is a disadvantage where the machine is stored in a public garage. The more practical design is that which prevents the operation of the motor or use of gearset or clutch and allows the vehicle to be moved by hand, as to the washstand for example.

CADY AUTO-JACK.

Automatically Raises and Lowers the Automobile.

The Cady Auto Appliance Company, 755 Central avenue, Cleveland, O., is manufacturing the Cady Auto-Jack,

which is stated to be automatic in its action. It lifts all four wheels of the machine 1.5 inches clear of the floor without effort upon the part of the owner of the machine other than driving the car upon it. A small lever, easily operated, permits of removing the car from the jack when desired, and the maker states that a child can do the work.

The Cady Auto-Jack is constructed of steel and finished in aluminum. It is guaranteed against any defect in workmanship or material, and weighs, crated for shipment, 200 pounds. It is moderately priced and the maker points out that it will not only save its cost in tire economy, but it will be found to be decidedly useful in the maintenance of the machine.

BAKER DEMOUNTABLE RIMS.

Designed Especially for Ford Cars and Come Painted.

The City Auto Tire & Supply Company, 1200 Huron road, Cleveland, O., is marketing Baker demountable rims for the model T Ford car, and the design of these members is such that they may be applied readily. The equipment is shown in the accompanying illustration and comprises four wheels with rims attached and one extra rim. The new wheels are nicely painted, striped and varnished, and the usual brace wrench and 24 new hub bolts are included.

To attach the wheels the nuts and bolts of the old members are removed and the hubs driven out. The hubs are then inserted in the Baker wheels; the new hub bolts fitted and the nuts put on and tightened. The rims utilize 30 by 3.5-inch tires, the maker pointing out that this arrangement makes for convenience as well as tire economy. The wheels are hickory and the rims are made by the Universal Rim Company.

ECONOMIZING TIME IN LOADING TRUCKS.

Novel Use of Overhead System, Combined with Specially Designed Body Equipment, Minimizing Labor and Delay, by California Wholesale Grocery House.

ECONOMY is a relative term. Business men who have given careful consideration to the subject of motor transportation are readily convinced that economy and efficiency are very closely related. In other words, there are certain lines, at least, in which it is possible to effect a saving over horse drawn equipment only when the motor truck can be utilized to its fullest capacity, particularly with reference to time. This applies to practically all lines, when it becomes a matter of the greatest economy.

Within the past few years wholesale grocers have given unusual attention to the question of

ever, it is extremely essential that the truck shall be kept busy, and to this end many interesting plans have been devised. One of these is indicated by the accompanying illustrations.

The system is that employed by M. A. Newmark & Co., Los Angeles, Cal., and by its use it is stated that the company saves at least 45 minutes in loading each vehicle. In addition, the handling of packages is still further reduced, requiring the services of a lesser number of men for a given amount of work, and eliminating the danger of making mistakes, since it is possible to make up orders and check them ahead of time

without confusion and hurry at the last moment.

In the first place, this company designed removable truck bodies, these virtually being hand trucks mounted on wheels of their own. Two of these are assigned to each chassis, a dummy wooden frame being fitted to the chassis frame as indicated in the foreground of one of the illustrations. These are lifted into and out of position by means of a telfer as shown. The other photograph reproduced herewith presents the overhead conveyor system, which is installed through the building, including the different elevators, so that the small trucks can be placed in position wherever wanted.

position wherever wanted.

In practise the small trucks are loaded while the motor trucks are on a delivery trip, and as fast as the orders are received, by mail or over wire. When the motor truck returns the telfer picks up the empties and replaces them with filled receptacles in waiting, and there is almost no delay.

As will be noted by the accompanying illustrations, the telfer equipment includes an electric motor, with provision at the rear for the operator, who occupies a convenient seat and directs the placing of the hand trucks. Suitable

Indicating the Overhead System Employed to Place Hand Trucks in Various Parts of Newmark Wholesale House.

highway haulage. In many instances their travelling salesmen have been supplied with automobiles, the better to cover their territory and reach customers without depending upon railroad schedules. Possibly it was the success which attended this innovation which caused the heads of such firms to investigate the possibilities of motor trucks.

The advantages of motor equipment in this field are many, including the ability to make quick deliveries at the door of the customer, and the elimination of freight charges and the necessary additional handling of the packages. How-

belts, running over pulleys are arranged to pick up the trucks and hold them suspended while the electric motor conveys them about the warehouse. Several of these telfers are employed to accommodate the needs of the company.

The Newmark house is not only one of the first concerns on the Pacific Coast to use motor trucks in its business, but it is one of the largest users of such vehicles in Los Angeles. As soon as it had been demonstrated to the satisfaction of its officials that mechanical transport offered a means for increasing the range of action, practically all of its horse drawn wagons were replaced by automobile equipment.

For more than a year now it has been operating a fleet of 11 GMC trucks of 3.5 and five tons capacity. The overhead conveyor system described above was installed soon after the decision to utilize such vehicles was made, and this plan has played a very important part in the success of the enterprise. According to the officials of the company it has increased the efficiency of the trucks at least 30 per cent.

EMPIRES IN DISTANT LANDS.

Indianapolis Product to Be Displayed in Australia and the Orient.

During the New York show in January, arrangements were made to ship the entire exhibit of Empire cars, made by the Empire Automobile Company, Indianapolis, Ind., to Sydney, Australia, where it will be on display at the mo-

Telfer Loading Hand Trucks on Specially Designed Commercial Car Chassis in Service of M. A. Newmark & Co., Los Angeles, Cal.

tor vehicle exhibition to be held in the near future. Another Far East show, at which Empire cars will be represented, is that to be held in Semarang, Java, next month.

The exhibition of the Empire Little Aristocrat, as the product of the company has come to be known, in these foreign displays, is an indication of the worldwide business which this company has secured. During a recent six weeks' period shipments of Empire cars were made to England, Scotland, Ireland, Wales, France, Portugal, Sweden, Denmark, Norway, Finland, Australia, Tasmania, New Zealand, Philippines, three cities in India, Malay Peninsula, Java, Japan, Arabia, South Africa, Argentina and Chile.

G. E. Warner, New Berlin, N. Y., who recently opened a garage, accessory and repair business under the name of the New Berlin Motor Supply Company, has been instrumental in the organization of the New Berlin Automobile Club, with 20 charter members. F. E. Holmes is president and J. T. Ball, secretary.

Fleet of 11 GMC Trucks Used by M. A. Newmark & Co., with Overhead Conveyor System Described.

REGAL LINE INCLUDES FOUR MODELS.

THE Regal line of motor cars for the 1914 season comprises four models, three of these being of the well known underslung type and

Right Side of Regal Model T Motor Showing Location of Rushmore Starter and Method of Meshing Pinion with Periphery of Ring Gear Flywheel.

the fourth chassis being termed an overhung by the maker, the Regal Motor Car Company of Detroit. The last named, the model C, differs from the conventional spring suspension in that the four springs are suspended from the undersides of the axle, which not only lowers the frame, but provides a straight line drive, as well as makes for a factor of safety when travelling at high speeds.

The chassis of this model is fitted with attractive streamline type of five-passenger body, and the upholstery and appointments are in keeping with the rich design. The equipment is most complete and includes a Rushmore motor starter and lighting dynamo, two separate units. Electric lighting and motor starting are standard equipment on all Regal models.

The L head motor is larger than that used in the other chassis, having a bore of four inches and stroke of five, and the cylinders are cast en bloc with the intake passage cored out between the second and third cylinders. It is rated at 35 horsepower. The exhaust is cared for by a detachable manifold.

A three-bearing crank and camshaft are utilized, the bearings being of liberal size and supported in the conventional manner. The crankcase is divided, the upper half being reinforced to give rigidity, and the

lower half being easily displaced. The motor is suspended on the main chassis frame by four arms cast integral with the engine base. A constant level splash system of lubrication is employed, a plunger pump driven by an eccentric on the camshaft forcing the lubricant to the bearings, and the connecting rods dipping into it about .125 inch.

The ignition system is dual, batteries and a magneto, and cooling is by thermo-syphon with fan. The clutch is a cone, leather faced, and the gearset located on the rear axle is of the selective type providing the usual three forward speeds and reverse. Left hand drive and centre control are standard with all Regal models.

Two universal joints are employed, one in the housing attached to the forward end of the transmission case and the other just back of the clutch sleeve. The housing of the drive shaft serves a double purpose, in that it encloses the driving member and functions as a torque tube. Heavy radius rods extend from the rear axle housing to upright brackets riveted to the centre cross member of the frame. The last named member is made of tested, rigidly inspected pressed steel channels of the conventional type, and has a kickup at the rear. The front axle is of the I beam section type, and the rear semi-floating. High duty roller bearings are utilized and the axles are nickel steel.

The service brakes are of the external contracting type, operated by pedal, the expanding emergency being actuated by the usual hand lever. Both sets are liberal in size and are adjustable. The steering gear is of the irreversible worm and gear type and means are provided for taking up lost motion.

The Regal Motor Car Company calls particu-

The Regal Line Comprises Two Five-Passenger Touring Cars, a Two-Passenger Roadster and a Coupe—The Regal Underslung Spring Suspension Is Featured, with the Exception of Model C, Which Utilizes Overhung Springs.

lar attention to the springs and the method of suspension. The front springs are semi-elliptic, 38 inches long and two wide, while the rear are three-quarter elliptic, 46 inches long. These dimensions, coupled with a wheelbase of 116 inches, not only make for maximum comfort when traversing rough roads, but for durability.

The tire size is 34 by four inches and demountable rims with one extra members are standard equipment. Provision is made for carrying spares at the rear of the chassis.

The Rushmore motor starter has been described in these columns. It is operated by a button located on the dashboard, convenient to the driver. The lighting system eliminates the side lamps, a dimming attachment being provided in the headlights and controlled from the seat. All trimmings are nickel, and the equipment comprises an electric horn, mohair top, special curtains, top boot, rain vision ventilating windshield, speedometer, muffler cut out, tire irons, tools, etc. The standard color is dark blue with light blue striping.

The underslung models comprise the N, a two-passenger roadster; the NC, a three-passenger coupe, and the T, a five-passenger touring car. With the exception of the tire equipment, the coupe being equipped with 33 by four-inch tires, and the others with 32 by 3.5, the chassis details are similar. The motor is of the L head, en bloc type, with a bore of 3.75 inches and stroke of 4.5.

The roadster was designed to meet the demand for a compact, comfortable, roomy fast car, one adapted for business as well as pleasure. Its lines are long and sweeping, and the low suspension, due to the Regal underslung springs, provides a large factor of safety when travelling at high speeds. This has always been one of the qualities of the Regal chassis emphasized. Many details have been refined. The fuel tank at the rear is partly enclosed, and as with the model C the side lamps have been eliminated.

The coupe is patterned after the latest vogues in coach work; is exceptionally large, and seats comfortably two persons on the rear seat, provision being made for an extra passenger by a front folding seat. The body is low hung, following Regal practise, and large single plate windows are utilized. All the main windows and glass front are adjustable, affording suitable ventilation for all seasons of the year. The seat and lower part of the body are finished in buffed leather, the upper part and ceiling being in blue broadcloth. The appointments are in keeping with the rich design.

The model T is a five-passenger touring car

providing room for five large persons. There is ample space between the front and rear seat, and the upholstery is deep and comfortable. All of the underslung models have an equipment that leaves nothing to be desired.

NEW JERSEY CYCLECAR CLUB.

Will Hold Its First Run from Newark to Dr. Percival's Farm on Memorial Day.

The formation of cyclecar clubs is quite the order of the day. During the recent Boston automobile show, Dr. Charles G. Percival, the well known automobile publicity man, helped form the Cyclecar Club of New England. Immediately upon his return to New Jersey, which is now his home state, he found the representatives of 10 makes of cyclecars ready to organize the Cyclecar Club of New Jersey.

A meeting of those interested was held in Newark, St. Patrick's Day, and the following officers were chosen:

**Dr. Charles G. Percival, President,
Cyclecar Club of New Jersey.**

Charles G. Percival, Teaneck; first vice president, William Bouldin, 3rd., East Orange; second vice president, H. Coulson Fairchild, Montclair; secretary, C. T. Chatfield, Newark; treasurer, Chauncey Batzle, Bloomfield; board of governors, G. A. McLaren, Newark; H. M. Condict, East Orange; T. H. Blackmore, Allendale; Harvel Batzle, Bloomfield. The club voted to engage permanent quarters at 223 Halsey street, Newark. It was decided to hold the first club run from Newark to President Percival's farm at Teaneck, Memorial Day.

SUGGESTIONS FOR THE NEW CAR OWNER.

Adjusting Service and Emergency Brakes on Cadillac Car--Simple Method of Constructing Fuel Measure--Adjustment of Clutch on Model 31 Empire.

THE general practise is to fit two sets of brakes to the car and to utilize the external contracting type for the service members and the internal expanding for the emergency, as with the Cadillac car, for example. Next to the steering gear the brakes are important factors in the operation of the machine and should be inspected from time to time; adjustments made and the friction material renewed if worn down to the rivets.

While either set should be capable of locking the wheels, it is bad practise to so use them, and they should only be employed thus in a case of emergency. The experienced operator will utilize the throttle and use judgment in its ap-

Components Utilized in Adjusting for Wear of Service and Emergency Brakes on Cadillac.

plication when about to slow down for a stop, for example.

Sometimes the brake lining will become dry after continued service, gripping the drums too quickly. A mixture of graphite and oil smeared over the friction material will generally cure the trouble, but it should be used sparingly. If applied properly it will not interfere with the efficiency of the brakes.

That the operating mechanism of brakes will require lubrication from time to time will be made evident by a study of an accompanying drawing which shows the components of the Cadillac external contracting and internal expanding brakes. It will be noted that the service members (external) comprise bands that are contracted by a lever W, which, when moved

forward, draws down the upper half of the band and moves upward the lower half, by means of the screw member T V.

Adjustment of the service brakes is made by turning the screw S until that part of the band opposite it is brought as close as possible to the brake drum without touching it. Next adjust the nuts T on the eye bolt until the lower half of the band lining just clears the drum. The nut V on the upper end of the eye bolt is so adjusted as to bring the lever W to the position shown in the drawing when the brake is applied. With the brake released the clearance between the lining and drum should not be over approximately .03125 inch, and if more exists, it may be reduced by the set screw X in the rocker lever Z.

The internal brake is constructed to be adjusted for clearance between the internal band and the drum, without displacing the wheels. Jack up the axle so that the wheel will clear the ground, permitting of revolving it by hand, and remove the cover A from the opening in the brake drum. This can be accomplished by unscrewing the lock nut B and turning the bolt to the left about a quarter-turn until the clamping bar D is released.

Next, rotate the wheel until the opening registers with the adjusting screw E. Turn the last named member until that part of the brake lining in line with the screw E is brought as close to the inner surface of the brake drum as possible without touching it. Turn the wheel until access is obtained to the six locking screws N, and loosen these. Turn the two adjusting screws F F, which have right hand threads on one end and left on the other, until the centre of the pin G stands about .75 inch back of an imaginary line drawn through the centres of the two pins H H, when the brake is applied.

With the brake released, adjust the screw I in the lever J and the stop screws K K until the lower and upper parts of the brake band lining clear the drum about .03125 inch. The three coil springs M should have sufficient tension to hold the brake band sideways, and against the stop screws K K so it will not rattle. It is important that the screws N be locked after completing the work, also that the cover of the opening in the drum be replaced and fastened securely.

It is equally important to make sure that after

adjusting the brakes the lining material does not drag. Run the car a short distance and place the hand on the brake drums. If they are heated,

Showing Capacity of Model T Ford Fuel Tank in Gallons, Corresponding to Inches and Fractions Thereof.

it will indicate that the friction material is making contact with the drums and an inspection should be made to ascertain the fault. The linkage of the brake mechanism should be lubricated and compensation for wear should not be made by adjusting the pull rods.

MEASURING TANK CAPACITY.

The average new owner wishes to learn how many miles he is obtaining to a gallon of fuel and if accurate data be desired it is necessary to know the exact capacity of the tank. This is generally stated in the instruction book or catalogue, but, in the opinion of the writer, if fine results are to be obtained, it is a good plan to check the capacity of the fuel container.

This may be accomplished by one of two ways—by figuring its capacity or by actually demonstrating this point. The latter method is simple and consists of emptying the container of all fuel and refilling it. This plan has an advantage in that it affords an opportunity to clean the vessel, and even with new cars foreign elements have been known to exist in the fuel tank.

Having emptied the container it is a simple matter in replenishing the supply of fuel to check the height of each gallon of fuel. Take a piece of soft pine, which is easy to work, and cut it to about one inch wide and from .25 to .375 inch thick. It should be sufficiently long to touch the bottom of the tank and extend a couple of inches above the top of the filler cap. Smooth the stick by sandpapering.

Some paint the measure with black paint, but a simpler method is to use powdered graphite, rubbing it on well and polishing it afterward. This will leave a smooth, black surface, not affected by the action of gasoline and one on which the fluid will show clearly.

With the fuel tank empty, pour in exactly one gallon of fuel, then insert the measure and note the height, marking it. In placing the measure in the tank, insert it gently so as not to splash the liquid above the normal level. Add another gallon and mark the measure, repeating the operation until the tank is filled. This method was utilized by the writer in making a measure for a tank which was of peculiar shape.

In an accompanying illustration is presented a diagram issued by the Ford Motor Company for making a measure for the fuel tank used on the model T Ford car. The relation between the height at which the liquid stands and the volume it occupies is clearly depicted, and by making a stick and marking it according to the diagram, the motorist will be able to learn how much fuel is in the container and how many miles have been obtained from the gasoline used. All fuel measures should be kept clean and never placed in the tank if dirty. With some motors the opening of the spraying nozzle is so fine that a small particle of dirt will clog it easily.

EMPIRE MODEL 31 CLUTCH.

The clutch is an important factor in the operation of a motor vehicle. In these days of refinement in mechanical construction a well designed clutch rarely gives trouble if the instructions of the maker are followed as to care and maintenance.

Some owners have a habit of not looking after the components of the chassis until trouble is experienced, believing it is best to leave all parts alone until they actually require attention. This is an error, for there is a certain amount of work that is necessary if efficiency is to be maintained and the repair bill avoided. This point is emphasized

Adjustment of Clutch on Model 31 Empire Is Made Easily, Because of Simplicity of Construction.

phasized in the instructions given by the Empire Automobile Company as to the care and maintenance of its 1914 model 31 machine, and similar

views are held by practically every manufacturer.

The period of adjustment of a clutch will depend upon the service it has been subjected to. For example, some drivers use the clutch intelligently, while others abuse it. Properly used a clutch will perform its function for a considerable length of time.

If it is found that the clutch slips, it is advisable to try simple methods before adjusting it. First drain off all of the old lubricant, then replace the plug and fill the clutch compartment about half full of kerosene. Next, alternately engage and disengage the clutch to allow the fluid to penetrate to all parts of the construction, and it is a good plan to run the motor during this work. If the car is standing still, be sure to place the gear lever in neutral. Drain off the kerosene and refill the clutch compartment with lubricant, then try the action of the clutch out on the road. If it does not act satisfactorily it must be adjusted to eliminate slipping.

One of the Maxwell Specials Constructed Under the Direction of Ray Harroun for the 500-Mile Race.

To increase the clutch spring tension, displace the clutch cover and turn the motor over until the locking plunger A, shown in an accompanying illustration, appears. This plunger member pins the flywheel and the compression plate B together. Pull out the plunger and turn it a quarter-turn, which will disengage it. Next, disengage the clutch and hold it out by using a stick of proper length, bracing the stick against the front seat heel board.

By utilizing a bar or wrench, denoted by C in the drawing, the compression plate B may be rotated to the right until the locking plunger A coincides with the next hole D in the flywheel. Return the locking plunger to its seat and try out the action of the clutch. If it continues to slip, another adjustment must be made. It should be borne in mind that the adjustment must not be made with the clutch engaged, as the adjusting

plate B cannot be rotated in either direction with the clutch in.

To decrease the spring tension, remove the plug in the flywheel housing and turn the motor over until the small hole in the rim of the flywheel shows. Insert a bolt or pin in this hole to lock the flywheel and proceed exactly as outlined for tightening the clutch, but, of course, the compression plate is rotated in an opposite direction—to the left instead of right.

THE THREE MAXWELLS.

Machines Designed by Ray Harroun Nearly Ready for Their Test Trip.

For some few weeks it has been known that Ray Harroun, well known in automobile racing fields and as the inventor of the Harroun carburetor, was working on three Maxwell cars, scheduled to take part in the forthcoming 500-mile international sweepstakes race on the Indianapolis speedway, Memorial Day. It is now announced that these machines are nearly ready for their test trip, and that Harroun confidently expects they will develop sufficient speed to encircle the track, 2.5 miles, in 1:37, which is one second faster than any car has yet negotiated a lap on that course. One of the machines is shown in an accompanying illustration.

Unusual interest attaches to this announcement, from the fact that the Maxwell cars were withdrawn from racing some two or three years ago, when they were being produced under the direction of the old United States Motor Company. Of course it is well known that the men now in charge of the Maxwell Motor Company have very different ideas concerning a number of things, and the matter of racing appears to be one of them.

Maxwell Motor Company officials are quoted as saying that, while the company enjoys a large export trade as it is, it intends to go after foreign business as vigorously as that at home. Racing, or competing with well known machines of foreign make, is held to be one of the satisfactory ways of accomplishing this end. Therefore, these specially designed cars have been constructed to compete with the foreign machines entered in the world's long distance track race of the year.

WHAT MAINTENANCE COSTS.

Interesting Figures Revealed by KisselKar Owner in Madison, Wis.

Many times prospective owners seek reliable information as to the maintenance cost of an automobile. Chauncey E. Blake, a well known lawyer of Madison, Wis., who has kept an accurate record of such costs, including every possible incidental expense, has forwarded some interesting data on this subject to the Kissel Motor Car Company, Hartford, Wis.

Mr. Blake purchased a 1912 KisselKar 40 in December, 1911, and placed the machine in service in March, 1912. During that year his mileage was 5128.6, and in 1913, 3740, making a total of 8868.6 miles. He states that it has been in use in all kinds of service; that is, cross country driving, shopping and doing errands about the city, and in all seasons.

His figures show that since it started in service this car has cost just under 2.4 cents a mile for gasoline, this being the average under favorable and unfavorable conditions, touring or doing shopping with the car standing at the curb and the engine running free. The cost for oil and lubricants has been 24 cents a mile. Tires figure at 4.8 cents a mile, and this, he says, has been increased by reason of accident and faulty tires. He is now figuring about 4200 miles a casing.

The cost of repairs, exclusive of time, has been \$38.25, of which \$27.25 was expended for a coat of varnish. Insurance figures at \$37.50; license, \$10; lighting, such as gas tanks, new lava tips, oil, etc., \$18.70; electricity, \$6; incidentals, including anti-freezing solutions, rubber tubing, subscription to highway fund, motor magazines, etc., \$26.70. The total charges for time against the car aggregate \$144.74. This includes washing, delivery and occasionally a driver.

At the time the letter was written, the car was undergoing its first general overhaul, and Mr. Blake states that he was surprised to find that the bearings, gears and all working parts showed absolutely no wear.

AN ENDLESS SAND BELT.

Novel Device in Use of Overland Stage Crossing the Colorado River Basin.

Necessity is the mother of invention. Some time ago George L. Johnson of Holtville, Cal., purchased an automobile with which to operate a stage line between that town and Yuma, Ariz., a round trip distance of 56 miles, a greater por-

tion of the route being across the great desert of the Colorado river basin. At first he attempted to make use of the regulation strips of canvas, which are commonly spread for machines to travel over, where long stretches of sandy trail are encountered. He soon found, however, that these were impracticable, for the reason that there was so much sandy waste he was busy most of the time spreading canvas.

Thus was the necessity established. Mr. Johnson invented the sand belt, which consists of an endless belt of 12-inch traction engine belting, so arranged on light rollers that it glides over and under the wheels of the car as the machine progresses, as indicated by an accompanying illustration. It may be added that the photograph was taken when the stage was stripped for a race at the fiesta in Holtville, New Year's Day. It won, too.

When used as a stage, the machine carries a

George L. Johnson's Sand Belt Attached to Rear Wheels of Overland Stage in California.

five-passenger body, and sand belts are employed on the front wheels as well as those at the rear. The stage line was established as the result of a natural demand for some reasonably rapid means of transportation, there being no direct train service between the two points. The automobile lays its own track of endless belts throughout 56 miles daily, for which service, Mr. Johnson receives \$7 a person one way, or \$12 for the round trip. Application has been made for a patent on the sand belt, so it is expected that it will add another percentage to the profits of the line.

Benjamin Briscoe, president of the Briscoe Motor Company, New York City, while at the factory in Jackson, Mich., recently, stated that the first Briscoe cars will be ready for delivery by April 15.

WITH THE CYCLECAR MANUFACTURERS.

Prospective Purchasers Should Be Informed as to Their Ability to Secure Machines If Ordered---Constructional Details of Some Models Announced Recently.

CONDITIONS surrounding the establishment of the cyclecar branch of the industry have been such as to foster extravagant claims for a number of makes of machines which have as yet progressed but little, if any, beyond the blue print stage. That the public is eager to secure a practical motor vehicle that can be operated at small cost, such as the cyclecar is claimed to be, is decidedly evident from the flood of inquiries which has made its appearance since the announcement of the first experimental models.

Engineers, who have been working on cyclecar designs, have had the benefit of the experience accumulated through the production and use of automobiles. However, the public cannot expect that exactly the same application of prin-

of the manufacturer to make delivery of cars.

Little is to be gained by an attempt to mislead the public. There is a certain market for the satisfactory cyclecar, and those who are intent upon meeting this demand should find little trouble in disposing of their products, but the sale of stock in a cyclecar company is an entirely different matter. It may be somewhat difficult to differentiate between the manufacturer who is honestly trying to provide a machine which shall prove satisfactory in the hands of owners and promoters who are making the most of the opportunity afforded by the widespread interest in such vehicles to make money in the easiest way. The Automobile Journal hopes to present, in each instance, so far as it is able to secure such facts, information which will enable the reader to make his own deductions.

IMP ON CHARLES RIVER.

President E. P. Blake of the Cyclecar Club of New England Makes Fast Time.

E. P. Blake, Boston, and His Imp on Ice of Charles River.

ciples can be made in a machine designed and constructed along the simplest lines. Theories have been advanced, and some of these apparently have been substantiated in road tests, but conservative automobile men are convinced that their practicability cannot be determined beyond question until cars have seen service in the hands of users.

From the first, The Automobile Journal has sought to lay before its readers all the information available concerning these newer machines. It has presented such details and mechanical specifications as it has been able to secure from those who have sought to enter this field, and it proposes to continue this practise. It has felt that prospective buyers should be in a position to at least form some opinion as to the ability

Apparently the history of the cyclecar branch of the industry is to be largely in the nature of a repetition of that of the automobile itself, at least insofar as the publicity campaign is concerned. In days gone by, attention was directed to automobiles by the performance of unusual tasks, therefore, the cyclecar may be expected to emulate the example of its older brother, so to speak.

An accompanying illustration shows E. P. Blake of Boston, president of the Cyclecar Club of New England, in his Imp on the ice of Charles river. Just before the opening of the Boston automobile show, Mr. Blake drove this machine five miles out and return on this ice, and is said to have covered the distance in 12 minutes; the last mile in 53 seconds.

What may be considered a decidedly more interesting demonstration of the practicability of the Imp lies in the statement that Mr. Blake, who is the New England distributor for this make of cyclecar, has used one of these machines daily for the past six weeks in driving to and from his home at Tufts College hill, Medford, Mass., and his office in Boston.

MORE ABOUT THE BANTAM.**Quantity Production Will Depend upon the Manner in Which It Is Received.**

It will be remembered that one of the new models revealed at the recent Boston automobile show was the Bantam, made by the Bantam Motor Company of that city. Among those actively identified with this concern is F. J. Tyler, who is well known in the New England field through his connection with the sale of Maxwell cars, both as agent for the old Maxwell-Briscoe Motor Company and later as branch manager for the United States Motor Company.

Mr. Tyler explains that every effort has been made to produce a cyclecar which shall represent the best of material and workmanship, and he asserts that components utilized have the same strength as some of those employed with the small Maxwell model produced a few years ago. His purpose in calling attention to this detail is to indicate that while the Bantam weighs but 700 pounds, it is contended that it has a factor of safety which would meet the demands of a car of twice its weight.

The first models of the Bantam were produced in the factory of the Lenox Motor Car Company in Boston, although that company has no interest in this machine. It is probable that this plant will be used for the present, since Mr. Tyler states that no attempt will be made toward quantity production until the public has had ample opportunity to test the cars in actual service. This is taken to mean that only a comparatively few machines will be made at first, perhaps 100, and that no steps will be taken to secure permanent factory facilities until every detail concerning the little car has been thoroughly worked out.

The Bantam is a true cyclecar of the roadster type, seating two passengers side by side, with the driver at the left and the control levers in the centre. There is only one door, at the right. At the rear is a compartment for luggage, which also provides room for a set of dry cells supplying current for electric lights front and rear. The wheelbase is 86 inches and the tread 46.

The motor is a two-cylinder, air-cooled V unit, with bore of 3.5 inches and stroke of 3.75,

rated at 9-14 horsepower. Power is transmitted by friction discs and chain to a semi-floating rear axle, in which the usual differential is incorporated. The wire wheels are fitted with 28 by three-inch tires.

ANOTHER CLEVELAND MACHINE.**Company Will Be Formed to Produce Car Designed by English Engineer.**

Announcement is made from Cleveland, O., that after two months of experimentation the Cleveland cyclecar will make its appearance in the near future. A company, to be known as the Cleveland Cyclecar Company, is to be organized with capital of \$150,000, those interested in the venture being Robert Clark, W. E. Burns and W. H. Noyes. Clark is said to have been engaged in cyclecar development in England.

Bantam Roadster Design, Which Is Being Produced in Limited Numbers by Boston Concern.

The machine is to be with wheelbase of 96 inches and tread of 36, equipped with interchangeable bodies, of the roadster and package delivery type. The motor will be a four-cylinder unit. Final drive will be by belt. Other details have not as yet been made public.

MERCURY ELECTS OFFICERS.**Stockholders Hold First Formal Meeting and Men Give Up Other Active Connections.**

The first formal meeting of the stockholders of the Mercury Cyclecar Company, Detroit, was held Feb. 21, at which the following officers were elected: President, W. J. Marshall; vice president, H. A. Burnett; secretary and treasurer, R. C. Albertus. Henry H. Henderson also has joined the forces of the company as production

Tandem Seated Greyhound, Which Follows Bedella Example, Locating Driver at the Rear.

manager and has assumed his new duties.

According to a recent announcement of the company, Mr. Albertus and Mr. Marshall, who have been identified with the automobile business for a number of years, have given up all other active connections. Burnett has been associated with the Digestive Ferments Company, Detroit, for a number of years as sales manager. He does not give up his other connections, and acts largely in an advisory capacity. It is further stated that the first carload of Mercury cyclecars left the factory March 4, and that it is anticipated that carload shipments will be made at regular intervals from now on, going to all parts of the country.

NOVEL SEATING ARRANGEMENT.

Real Cyclecar Provides for Three Passengers and Has Motor at the Rear.

A true cyclecar seating three persons is announced by the H. Paul Prigg Company, Anderson, Ind., which is said to have acquired the plant formerly occupied by the Spring Steel Fence & Wire Company at Brown street and the Central Indiana railway. This is termed the Real, and has wheelbase of 100 inches and standard automobile tread, 56 inches. The driver sits in a single seat in front, while the rear seat is 33 inches wide, affording ample room for two persons. In this respect, at least, the Real occupies a distinct place in the American industry.

The motor is a Wizard, two-cylinder, air-cooled unit, with bore of 3.375 inches and stroke of 3.875, being rated by the maker at 10 horsepower. This is mounted at the rear of the

car. A specially designed friction transmission affords any number of speeds either forward or reverse, and final drive is by Peerless V belt, fabric covered, operating on short centres and small pulleys.

The frame is of spruce, reinforced with truss rods and armored corners. Suspension is by semi-elliptic springs, mounted on swinging shackles. Wheels are of wire, fitted with 30 by three-inch tires. The steering gear is of the standard rack and pinion type, and a mechanical starter is supplied, this being operated from the seat. A top, windshield and electric lights are listed as extra. It is added that a special type of delivery body can be furnished upon order.

GREYHOUND FROM TOLEDO.

Tandem Seated Machine Which Made Its Appearance During Recent Show in That City.

The Greyhound made its appearance during the recent automobile show in Toledo, O. It is the product of the Greyhound Cyclecar Company, with offices in the Nicholas building, in that city. The one model which has been made public has tandem seating, with wheelbase of 104 inches and tread of 38. No weight is given, but such details as are available would seem to place it in the true cyclecar class.

The motor is a De Luxe two-cylinder, air-cooled unit, presumably of standard dimensions. Ignition is by the Atwater Kent Unisparker system. Power is transmitted by friction discs and V belts, to the rear wheels. All four springs are of the cantilever type. The wire wheels carry 28 by three-inch tires. Contrary to the usual

Real Accommodates Three Persons, with Driver in Single Seat in Front.

practise in this country, although following the example set by the original cyclecar, the Bedelia of France, the driver is located at the rear.

DETAILS OF THE RITZ.

Second Model Made Presents Features Indicated as Desirable After Experimentation.

Several months ago, announcement was made in these columns of the organization of the Ritz Cyclecar Company, New York City. The officers are: President, Carl D. Ritzwoller; vice president, S. Katsaurer; secretary, treasurer and general manager, A. Russell Smith. The experimental work has been carried on at 246 West 65th street, although it is stated that the concern proposes to move to a larger factory in the near future, or as soon as the plans for production will permit.

The present Ritz model is the second made by the company, and is said to represent changes which have been adopted as the result of road tests and other experiments. The machine is a true cyclecar, with wheelbase of 98 inches, tread of 44 inches and weight of 650 pounds. The two passengers are seated side by side.

The motor is a two-cylinder, air-cooled V type unit, rated at 10-12 horsepower. Lubrication is by splash, with sight feed; carburetion by a Schebler, and ignition by a Bosch magneto. The transmission is by planetary gear, with a specially designed selective gearset, affording two speeds forward and reverse, and final drive is by shaft to a bevel gear rear axle.

MORSE HAS FRONT DRIVE.

First Model of This Type Makes Its Appearance from Pittsburg, Penn.

The Morse Cyclecar Company, 520 Lang avenue, South, Pittsburg, Penn., is announcing the Morse true cyclecar, which differs from standard practise, if this term may be applied to the cyclecar industry in America at this stage of its development, in that it employs a front wheel drive. In all other respects, it is of conventional appearance, the body seating two passengers tandem. The wheelbase is 105 inches and the tread 36.

The motor is a De Luxe twin, and power is transmitted to the front wheels through a planetary gearset, affording two forward speeds and reverse, and chain. The details of the steering mechanism are not fully disclosed in the preliminary announcement, although it is stated that the axle is fitted with universal joints in order to permit of utilizing the front wheels for both driving and steering. The body is suspended on cantilever springs, and brakes work on belt pulleys attached to the rear wheels, as well as on the front wheel drive.

NO STOCK FOR SALE.

Columbia, Ultimately to Be Front Wheel Driven, Announced in Seattle, Wash.

Right in the forefront of its announcement of the Columbia, a true cyclecar, by the American Cyclecar Company, Seattle, Wash., it is express-

Latest Model of Ritz Cyclecar, a Roadster Type Made in New York City.

ly stated that it has no stock for sale. Incidentally, it may be noted that the name of the company is the same as that located in Bridgeport, Conn., although there is no connection between the two. A factory is said to have been secured, this being a two-story brick building in the centre of the city. The officers of the company are: President, Daniel Murray; vice president, M. M. Cosh; secretary and general manager, George L. Grant.

The machine will have a wheelbase of 92 inches and tread of 40, seating two passengers side by side. The motor will be a two-cylinder, air-cooled, V type unit, with bore of 3.375 inches and stroke of 3.9. At present a friction transmission will be employed, with V belt drive to the rear axle, but application has been made for a patent on an entirely new front axle, providing for front wheel drive, and machines of this type will be constructed in the near future.

 gress of March 3rd, 1879.

THE MOTOR TRUCK.

The question of directing the attention of the business man to the merits of the mechanical transport has not been settled by the decision of the manufacturers to abandon the commercial vehicle shows in New York and Chicago. The success which attended the holding of the annual Boston motor truck show was such as to indicate that those who are giving consideration to this subject are anxious to take advantage of every opportunity to make comparison of the various types and models.

The Boston show was distinctive this year as being the only exhibition of its character of national prominence. Other cities held local displays, but the Boston show always has been, and probably always will be, of more than local importance. Apart from the fact that it is the

largest in the industry, it attracts patronage from a wide section—practically all of New England and a large portion of the Maritime Provinces of Canada.

The display just ended demonstrated very clearly the rapid development made by this branch of the industry during the last year. It is only a few years since manufacturers were installing a different type of body on a pleasure vehicle chassis and calling it a business wagon or truck. Today the product offered for the consideration of the business man is a specialized design, built throughout to meet the service for which it is intended.

Manufacturers, engineers and designers have made an exhaustive study of operating conditions. Motor trucks have now been in service sufficiently long to enable the collation of facts which show definitely the results that may be obtained. The efficiency engineer has made his appearance, and with him a trained corps of efficiency experts who are able to offer the business man information that can only be secured as the result of experience. There is a vehicle for every need, whether it be the delivery of small packages or the hauling of immense loads. The prospective purchaser has only to let his wants be known, and the industry is able to supply them.

AN ELECTRICAL AGE.

If it be true, as it would seem to be upon investigation of the history of the automobile industry, that each year has witnessed some particular feature in construction or design which has marked the vehicle of that year as somewhat distinctive from its predecessors, then 1914 is a year of electrically equipped machines. Electricity played an important part with the 1913 models, but analysis of the specifications presented in connection with the show season, just brought to a close, indicates that very nearly all makers either fit electric lighting and starting as standard equipment, or offer it as an extra.

With electric lighting and motor starting and electric gearshifts already installed on 1914 models, and the recent announcement of an electric brake and an electric transmission, it would appear that the 1915 car was to be about as near electrically controlled as was possible to make it.

RENAULT FOUR-WHEEL DRIVE TRACTOR.

Well Known Manufacturer Produces Entirely New Model, Incorporating Features Demanded by French Military Requirements--Details of Construction.

ALTHOUGH it cannot be held that front wheel driven trucks and trailers are entirely new, machines of this type having been on the market both in this country and abroad for a number of years, interest in them has been increased very materially of late, by reason of the prominence given them in the military trials in France this month. One of the newer designs is the Renault, made by Renault Freres, Billancourt, France, this having been built to comply with the army regulations, although in a general way it follows standard practise with this company.

The Renault pleasure car is well known in this country, and the truck bearing that name has been described fully in these columns. It is only necessary to state that the motor used in this newest vehicle is a four-cylinder unit, cast in pairs, with bore of 130 mm and stroke of 160 (5.1 by 6.29 inches). Cooling is by thermo-syphon, but instead of vanes on the flywheel and an air tight underpan, there is a fan at the back of the radiator, which is at the rear of the motor, as with all Renault machines, driven by belt running over a pulley just behind the flywheel. This fan is enclosed by an aluminum casing bolted to the rear of the dash, and has a central quick detachable cover to enable the driven pulley to be reached without taking down the entire casing. Louvers are cut in the rear portion of the bonnet, so that air can be drawn through the central radiator tubes, and a sheet metal V section guard is fitted between the rear cylinder and the cooler, so that the current of air going through the bonnet may be directed onto the central tubes and not onto the engine.

The clutch is of the inverted cone type, and there is a spring disc coupling between it and the gearbox. The whole of the mechanism between

the two is encased by an aluminum housing forming an extension to the gearbox. The lower half of this housing is fixed and the upper half is readily detachable. The arrangement allows the whole of the coupling and clutch withdrawing mechanism to run in oil, and has already been employed on other Renault truck models for more than a year.

Naturally, the gearbox is of special type. It affords four speeds forward and reverse, comprising usual primary and secondary shafts. On the primary is a central crown wheel engaging with pinion mounted on a shaft in the same vertical plane, this latter transmitting power through a front and rear propeller shaft to the respective axles. Each of the propeller shafts has a univer-

Renault Four-Wheel Drive Tractor and Two Trailers, Taking Part in the French Military Trials.

sal joint at each end. The axles are of the well known Renault design, comprising a one-piece forging with a central cradle, and with a cast steel cover on the driving end and a detachable aluminum cover on the other.

The front axle is bored out to receive the driving shafts, and, as the front wheels must steer as well as drive, there is an enclosed universal joint on the end of the shaft, within the steering pivot, as shown herewith, in the smallest illustration. Since a differential lock is necessary, this is provided by means of a lever in the change speed sector, with connections passing through the gearbox, left and right, to the two differentials.

There are three hand levers, as indicated, that

Universal Joint Arrangement in Renault Front Wheel Drive.

heavy platform at the extreme rear, and is driven by shaft and enclosed worm gearing. In addition to the external contracting brake at the rear of the gearbox, there is an internal expanding brake in each of the four wheels.

Cast steel wheels are employed, these being fitted with solid twin tires, 1055 by 130 mm (41.5 by 5.5 inches). Provision also has been made for the attachment of tire chains by fitting a series of hooks at intervals on the inner face of the rim, which permit the chains to be hooked on quickly whenever it becomes necessary to use them over the soft ground.

The steering gear is duplicated, of course. A worm on the steering column engages with a sector on a horizontal shaft, set just within the right frame member. This shaft has two worms, one of which engages with the sector carrying the lever arm for the front wheels, and the second with a corresponding sector and lever connected with the rear wheels. From these two points the control is exactly the same as on the ordinary models.

Suspension is by semi-elliptic springs, front and rear. Each of these has a sliding shackle at the rear, and is 5.5 inches wide. Towing hooks are fitted at the

at the left being the differential lock that in the centre, the change speed, and on the outside, the hand brake. The change speed lever also engages the capstan drive, which is at the left of the chassis, as viewed from the rear. The capstan itself is mounted on a

front of the chassis, and there is a quick action spring mounted coupling at the rear, and a very powerful sprag is hinged from the rear axle, in accordance with army requirements.

The largest illustration shows one of the Renault front drive tractors as fitted for competition in the military trials, hauling two trailers shod with steel tires.

SPECIAL RAYFIELD PRIZE.

Edwin Pullen, Winner of Grand Prize Event, Receives Pleasant Surprise.

It became known this past week that Edwin Pullen, who won the recent Grand Prize at the wheel of a Mercer car, being the first driver to pilot an American machine to first position in this international classic, was presented with \$250 by the Findeisen & Kropf Manufacturing Company, Chicago. It appears that Pullen used a Rayfield carburetor, made by this concern, and the gift was in the nature of an expression of the company's appreciation of his remarkably successful driving. Walter Findeisen explains the award as follows:

It gives us the greatest pleasure to say that Edwin Pullen selected the Rayfield carburetor of his own mind, and did so because he found in his experience that it was the best carburetor and most dependable for his purpose. He was not urged to use it, and therefore we are all the more gratified over his success, knowing that his own confidence in its dependability of service determined his selection.

Constructional Details of Renault Four-Wheel Drive Tractor: A, Differential Locking Lever; B, Change Speed Lever; C, Brake Lever; D, Foot Brake Adjustment; E, Fan Belt Drive; F, Enclosed Disc Universal; G, Rear Wheel Drive Rod; H, Steering Column.

K. K. Kornstein, St. Louis, Mich. Master Vibrators.

Ed. Note—The correspondence columns are open to all readers of *The Automobile Journal* and trade. Names of contributors will not be published if so requested, and when desired questions will be answered by mail. When the information is of an educational nature the editor of this department reserves the right to publish the question, but will make use only of the initials of the writer.

Horsepower Ratings—E. J., Newcomerstown, O.

Will you please explain why there is so much difference between the horsepower claimed by the manufacturer of some cars and the S. A. E. rating for the same? For instance, the Studebaker Four is claimed to have 35 horsepower and the S. A. E. rating for the same is 19.60. The Oakland claims 35 and the S. A. E. is 19.60. Are these manufacturers deliberately trying to deceive their customers or are they justified in making such claims, and how about the discrepancy between their ratings and the S. A. E.?

In analyzing the horsepower ratings in question it should be borne in mind that the S. A. E. formula is based on the bore of the cylinder and that the stroke is not considered. For example: A four-cylinder motor having a bore of five inches and stroke of seven, is rated at 40 horsepower by the S. A. E. formula and one having a bore and stroke of five inches is rated the same.

It is obvious that, all other conditions being equal, the motor with the seven-inch stroke will develop greater power because it has a greater piston displacement; that is, it is capable of containing a larger quantity of explosive mixture than the cylinder having a bore and stroke of five inches.

As previously stated, the S. A. E. formula does not consider the stroke, merely the bore, and this explains why there appears such a discrepancy between its ratings and those claimed by the maker. It should also be borne in mind that two motors of different makes or designs, and both having the same bore and stroke, will vary as to the horsepower developed.

The writer is of the opinion that the cars mentioned are conservatively rated by the manufacturers, as usually is true where the maker's rating and that of the S. A. E. fail to coincide. As an example of the wide variance which may take place, the Mercer four-cylinder motor has a bore of 4.375 inches and stroke of five. According to the S. A. E. formula the horsepower is 30.6, but the maker states that it must show a dynamometer pull of 58 horsepower at 1700 revolutions a minute before passing inspection. Other manufacturers rate their motors according to block tests, not by the S. A. E. formula, which does

not always indicate the actual horsepower that the motor is capable of developing.

The fact that the bore only is taken into consideration for registration purposes, may be said to be largely responsible for the increase in piston travel and decrease of the bore of motors used abroad, a practise that is being adopted generally in this country.

Changing Rims—F. R. N., Sioux City, Ia.

Having a machine equipped with clincher rims, and wishing to change these for the Firestone demountable type, what steps will be necessary and can I do the work?

To fit demountable rims to the wheels will require turning the wood felloe to a certain width and diameter. For example: The approximate wood wheel diameter for a 34 by four-inch clincher rim is 25.6875 inches, while that for the Firestone demountable is 24.6875 inches.

Assuming that the tire size is 34 by four inches the wood felloe C, Fig. 2, must be turned to 1.75 inches.

Fig. 1—Clincher Rim Dimensions.

As there is a slight variation in the circumference of the steel felloe band B, the proper circumference of the wood felloe should be determined by using a traveller on the inside of the steel felloe and noting the measurements. The wood felloe is then turned off, allowing about .125-inch draft, taking care that the outside circumference of the steel felloe band, when applied to the wheel, does not vary more than .046875 inch from six feet, 6.75 inches. This dimension is indicated by D.

To apply the steel felloe band, it is heated to about 550 degrees Fahrenheit and cooled slightly about the valve hole to prevent stretching at this point. The band should be applied with valve hole so placed that the bolt holes will not pass through the tenons of the spokes nor through the

felloe joints. The Firestone Tire & Rubber Company, Akron, O., supplies an instruction book containing illustrations showing the proper po-

Fig. 2—Showing Dimensions to Be Considered in Replacing Clincher Rims with Demountable.

sition of the bolt holes and valve apertures for different sized wheels. In fitting the felloe band, it should be flush with the face of the wood felloe. For drilling the bolt holes and for locating the brackets utilized, it will be essential to use a jig manufactured by the company for this work.

A specially constructed valve hole is necessary. Its front side must be straight, while the opposite side is tapered, making the finished hole .65625 inch at the inside of the wood felloe and .875 inch at the outside. The straight side is made by drilling a hole .65625 inch in diameter through the wood felloe, with the drill pressing against the front side of the valve hole in the steel felloe band. The tapered side is obtained by filing, burning or gouging out the wood to coincide with the .875-inch hole in the steel felloe band. The back washers used with the bolt assembly should fit snugly against the wood felloe and the steel felloe bands. It is necessary to drill a .3125-inch hole in the wood felloe at the point where the dowel pin, which is a part of the rim assembly and is riveted on the inner side of the rim base near the valve hole, is located.

From the above it will be seen that the fitting of demountable rims to wheels formerly equipped with the clincher type will require experience. It would be cheaper and decidedly more satisfactory to have the work performed by concerns making a specialty of fitting rims or by a competent wheelwright.

Overland Model 51—L. M. C., Hyman, S. C.

I have a model 51 Overland which needs new pushrods and bushings. Will you give me some information in the columns of your journal about putting these in, also the timing diagram for the motor?

To properly install pushrod bushings with the motor in question, it will be necessary to remove the lower half of the crankcase, also the camshaft, as the bushings are designed with a shoul-

der which makes it impossible to fit them from above. The bushings are retained in their correct position by locking screws which extend through the aluminum crankcase housing.

It is also necessary to install the pushrods from below at the same time the bushings are fitted, as the space between the aluminum pushrod bushing housing and the valve stem guide of the cylinder is not great enough to allow for the removal of the square type pushrod even after the adjusting screw has been entirely removed.

The flywheel fitted to the motor is 18 inches in diameter and at Fig. 3 is presented the valve timing diagram. This will not be necessary, however, as the flywheels of the Overland motors are marked, showing the opening and closing points for the different valves.

Before displacing the camshaft, mark the camshaft and crankshaft gears; that is, if these gears are not already marked. This will insure the correct replacement of the camshaft after fitting the new pushrods. To mark the gears, use a prickpunch, marking a tooth of the crankshaft gear that is in mesh with the camshaft gear, and a tooth on either side of the first marked member on the camshaft gear. The work of replacing the camshaft gear will be much easier if the valves are removed.

The periphery of the flywheel bears at various points the following marks: 1-4 Up, 2-3 Up, 1-4 I-O, 1-4 I-C, 1-4 E-C, 1-4 F-C, 2-3 I-O, 2-3 I-C, 2-3 E-C, 2-3 F-C. The marks 1-4 Up mean that the pistons of the first and fourth cylinders are at top dead centre; I-O and I-C, the opening and closing points of the intake valves, and E-O and E-C, the opening and closing points of the exhaust members.

Some of these figures and letters are shown in the drawing at Fig. 4, and it will be noted that centre of the last or fourth cylinder bears a prickpunch mark, indicating centre. Rotating the flywheel in the usual direction

Fig. 3—Timing Diagram of Overland Motor.

of travel and until the mark 1-4 Up registers with the mark on the cylinder, will obtain top dead centre for either No. 1 or the No. 4 piston.

Revolving the flywheel about 1.25 inches will bring the mark 1-4 I-O into line with that on the cylinder. This is the approximate point at which

Fig. 4—Flywheel Markings on Overland Motor.

the intake valve of the first or fourth cylinder should begin to lift. This can be ascertained by further rotating the flywheel until the valve has lifted, when it will be an easy matter to note

which of the two intake members is lifting. Move the flywheel back to 1-4 mark and check up the space between the pushrod and the valve stem.

As previously explained the valve should begin to lift when the mark 1-4 registers with the centre mark on the cylinder. Adjust the valve tappet to bring about this condition. The closing of the intake valve is checked or adjusted by rotating the flywheel until the mark I-C appears, and, similarly, the other intake members and exhaust valves are checked.

The opening and closing points of the valves in inches on the 18-inch flywheel are as follows: Intake valve opens 1.25 inches late and closes 5.96875 inches late. Exhaust valve opens 7.234375 inches early and closes 2.359375 inches late.

The maker of the Overland car recommends that the pushrods be so adjusted that there is twelve-thousandths (.012) of an inch space between the top of the pushrod adjusting screw and the end of the valve stem; about space enough to insert an ordinary calling card.

Acetylene Generator—G. F. C., Madison, Conn.

Can you furnish me the address of the maker of the Rushmore Prest-O-Lite gas generator? Do you know of any acetylene gas generator that can be attached to an automobile, that generates the gas by the action of dropping the carbide into the water automatically in place of the water dripping into the carbide? If so, where is it made and who is the maker?

The Rushmore generator is the product of the Rushmore Dynamo Works, Plainfield, N. J. The Prest-O-Lite gas tank is manufactured by the Prest-O-Lite Company, Inc., Indianapolis, Ind.

The writer does not know of any generator in which the carbide is fed to the water that is adaptable to service with a motor car. It would appear that the regulation of the dropping of the carbide and of its size would involve con-

structional details which would not be practical. The usual method with automobile generators is to regulate amount of water fed to the carbide.

"The General Trend of American Motor Design" will be the subject for discussion at the March meeting of the Metropolitan section, Society of Automobile Engineers, in the rooms of the Automobile Club of America, New York City, March 26. W. M. Power, who will present a paper and open the discussion, has been with the industry from its inception and has had active experience under a variety of circumstances which is held to have fitted him to view the subject in a large way.

TAIL LIGHT DETECTOR.

Dash Device for Warning Driver When Rear Lamp Becomes Extinguished.

In these days, when the ordinances regulating the operation of motor vehicles are being rigidly enforced, it is economy for the motorist to comply fully with the laws. The location of the tail light is such that it requires stopping the machine, getting out and walking to the rear of the vehicle when in doubt as to whether the lamp is burning. This applies to both electric and oil units.

The Harding Specialties Company, 755 Boylston street, Boston, has perfected a device termed the Boston tail light detector, which is a compact unit, designed to be mounted on the dash in plain view of the operator, and which instantly warns the driver when the tail light becomes extinguished. This is accomplished electrically, a red semaphore showing until the trouble is corrected.

One of the qualities of the design is the ease of installation, it being stated that anyone can attach and connect it in a few minutes, and without a knowledge of electrical connections. The Boston can be used with standard lamps and can be coupled with speedometer or dash lamps without additional wiring if desired. It comes in the following finishes: Black-nickel, brass, oxidized-black and nickel. It is moderately priced.

Boston Tail Light Detector.

TURNING CONCAVE AND CONVEX SURFACES.

CONSIDERABLE ingenuity is displayed by repairmen in overcoming various machining difficulties, and an instance of a useful lathe

Device for Machining Concave and Convex Surfaces on Centre Lathe: A, Path of Cutting Tool for Ball Seating; B, Swivelling Links for Procuring Radii; C, Path of Cutting Tool for Sphere.

attachment is described in a current issue of the *Commercial Motor*, an English publication. The repairman had occasion to replace parts of a badly damaged torque tube and ball universal joint, and, when he came to turn the ball and its seating, was confronted by a problem, inasmuch as the only machine available was a 12-inch centre lathe.

An accompanying sketch shows the attachment constructed and applied, and demonstrates how the concave and convex surfaces required were turned. The upper drawing shows the attachment for turning the concave surface; the lower depicts the ball being machined. The diagram underneath each lathe illustrates the path of the cutting tool.

The inventor of the attachments states that they were constructed without trouble. They consisted of flat mild steel strips, the sections being .5 inch by one inch. Six lengths were cut off to obtain the necessary travel, and at the base of the angle pieces were drilled two .375-inch diameter holes. The plain ends were drilled out .5 inch.

The swivelling connecting rods, two in number, were drilled out and tapped .5-inch Whitworth at each end, the centres being carefully marked out equal to the radius of the ball and spherical seating; that is, four inches. Permitting these to swing at the end of each angle piece

enabled the necessary arc of the cutting tool to be effected.

It will be noted that for either machining operation, one angle strip is bolted to the loose headstock of the lathe, and another piece to the top slide under the tool rest. Cross feed only is used, the transverse feed being free altogether so that without touching the handwheel the carriage may readily be pushed along the lathe bed. The cutting tool may then be made to follow the required circular path.

GROOVING OIL DUCTS ON LATHE.

Cutting in oil grooves in bearings with a chisel is not a satisfactory method and considerable time is lost in the operation. The proper method is to utilize an oil grooving machine, but these are not common in repair shops. In an accompanying illustration is presented an attachment for an ordinary lathe which the repairman who constructed the device states can be utilized to groove any size bush or bearing. The drawing is practically self-explanatory, but the chief points to be considered are that the arrangement should be bolted firmly to the lathe body and that the adjustable arm connecting the carriage with the horizontal disc should be parallel with the lathe bed at each end of its stroke.

The screw in the carriage holder must be

Attachment for Grooving Bearings on Lathe: A, Grooved Brass in Section; B, Arrangement of Drive; C, the Work Piece; D, Disc Drilled to Give Various Strokes; E, Adjustable Connecting Rod; F, Screw Which Is Removed to Allow for Free Travel.

withdrawn before commencing operations, so as to enable the carriage to slide easily in either direction. The drive must be so proportioned as

to enable the chuck to make one revolution while the tool is travelling the whole length of its stroke. An oil groove, after the outline of that shown in the small sketch, will thus be made to feed oil equally all over the bearing.

For example: Assume that a bush 1.5 inches long is to be grooved. The pin on the horizontal disc is set .625 inch out of centre; the connecting rod adjusted and the main carriage bed locked. The transverse screw is then removed

from the tool carriage and the grooving tool set about .125 inch inside the bush, and the lathe started.

The carriage being free to slide, the connecting rod will cause the tool to travel just 1.25 inches, and the gearing being so arranged that the chuck will make one revolution during the complete travel of the tool, an oil groove of the required length and pitch will be cut into the bearing.

MOTOR 'BUS AND EDUCATION.

How Widely Scattered School Districts Solved Problem of Higher Educational Advantages.

At distances varying from nine to 15 miles apart, in the vicinity of Fullerton, a prosperous town in Orange county, California, lie five school districts—Olinda, Placentia, La Habra, Randolph and Orangethorpe. Each of these districts has supported grammar schools for many years, but the problem of giving their graduates the benefit of a high school education was a very serious one. The motor truck has solved this difficulty.

About two years ago the five outlying districts combined with Fullerton in the formation of a union high school district, and three 1.5-ton trucks, with passenger bodies, were purchased in order to transport the pupils thereto. The system worked out so satisfactorily that the high school recently added two fine new 'buses to the passenger service. More than 100 pupils, or approximately half of the enrollment, are now being conveyed between their homes and the school in these vehicles.

The motor 'bus equipment represents a total investment of \$13,700. The chauffeurs are high school boys, who take turns at the wheel, and receive 50 cents a day for their services. There is a large garage on the school grounds, and a mechanic is employed constantly to care for the trucks and keep them in good condition. Special care has been taken to provide for the com-

fort of the scholars, some of whom travel no less than 26 miles a day in the 'buses.

As a result of the concentration noted, the Fullerton union high school district has been able to erect a magnificent group of buildings. The added attendance made possible by use of the trucks has provided the school with means to engage excellent instructors and to include new courses, which are a decided advantage to the pupils.

It may be added that the operating expense of the five vehicles is borne entirely by the union

One of the Newest Motor 'Buses Acquired by the Fullerton Union High School District in California.

school district and not by the individual students. The five motor 'buses have been in constant service, making regular trips over the several routes each school day. Such work as has been necessary, apart from the daily inspection and adjustment in the school garage during the school hours, has been done on Saturdays, and the success of the experiment, in the opinion of those who have been instrumental in its inauguration, has been such as to indicate that a similar system might be adopted with profit by other districts where conditions of this nature present themselves.

MOTOR EQUIPPED FARMING IMPLEMENTS.

Some Interesting Designs Revealed at Recent Agricultural Exhibition in Paris, Including Two Plows Involving New Principles, and a Mowing Machine.

WHETHER or not it is because the agriculturists of Europe are forced to give greater consideration to the so-called intensified farming, as has been stated by prominent foreigners who have visited America, it seems true that more attention has been paid to the matter of motorized agricultural machinery on the Continent than elsewhere. About four years ago the motor plow first made its appearance at the National agricultural show in France. The progress has been somewhat rapid, as indicated by the recent display in Paris.

Farm machinery was exhibited in the Esplanade des Invalides, and practically all of the available space was utilized. The list of self-

One of the most interesting new machines was the Moto-Aratrice, produced by Pavesi Tolotti, 18, Via Oglio, Milan, Italy. In this an entirely new principle is involved, in that the plowshares are pushed instead of being pulled. It is made in two models, one being rated at 16-20 horsepower and the other at 40-50. The accompanying illustration is that of the smaller model.

The front of the vehicle is mounted on a single, pivoted steering wheel, which is arranged to be raised or lowered to give the desired depth of the furrow. The two-cylinder slow running motor is placed at the driver's left, who sits over the gearbox. At the outer end of the shaft extending through the gearbox is a sprocket from which final drive is by chain to the right rear wheel. In this wheel is incorporated an eccentric drum or hub, which operates 12 stout shafts connected at their outer ends to double-pronged blades pivoted between the side plates of the wheel. The eccentric action of the wheel in motion causes these blades to project in order to provide traction. After leaving the ground, the eccentric action causes them to lie flat with the tread, until they pass the top centre.

The left rear wheel is said to follow the last share in the furrow, although this is not clearly indicated by the illustration. Provision is made for lowering or raising the frame at that point to keep the vehicle in a horizontal plane, and a brass indicator shows the amount of deflection and therefore the depth of the furrow. It will be noted that the three shares are carried on a frame extension securely riveted to the right main frame member.

Another interesting machine shown was the Amiot, made by Henri Amiot, 50, Rue Lesage, Rheims, France. This is termed a combined tractor-plow, in that the share frame can be removed and the remainder of the vehicle utilized as a tractor for various purposes about the farm.

Moto Aratrice, an Italian Machine Which Pushes Plowshares Forward Instead of Pulling Them.

propelled implements included not only plows of every description, but hoes, planters, mowing machines, and nearly everything used by the farmer. Of course, there were a large number of tractors of one form and another.

Some of the machines shown have been described fully in these columns. Among these were the Stock self-contained plow, made in Germany, and the Bauche hoe, made in France, both of which have enjoyed a wide sale on the Continent, and have only recently been introduced in Great Britain. America was represented in the show by the International Harvester Company's kerosene tractor and the tractors made by J. I. Case Threshing Machine Company.

In many respects it differs decidedly from standard practise.

The motor is a four-cylinder Abeille, mounted at the forward end under a hood, with the radiator in front and the fuel tank at the rear. This is rated at 40 horsepower. Drive is practically direct, there being only one speed either forward or backward, and power is transmitted to the 70-inch rear wheels by side chains.

A feature of the machine is the provision for turning the furrow either to the right or left, thereby making it unnecessary to go around the entire plot. A strong rigid frame at the rear carries six plowshares, three being above and three below, as shown in the accompanying illustration. Above this is a crane like girder, carrying a pulley at its outer end, over which is led a chain, by means of which the plowshare frame is hoisted and lowered, by the engine's power.

At the forward end of the plowshare frame is a train of gears, also operated by the motor, by means of which this frame may be rotated so as to bring either set of shares into action. This frame also is made detachable by removing two bolts. A yoke is then substituted, converting the forward portion of the machine into a tractor.

Among the mowing machines shown was an entirely new model, produced by S. Plissonnier, 234, Cours Lafayette, Lyons, France. The construction involves

the use of a long frame, with a 6-8 horsepower motor mounted at the front, over a single pivoted wheel. The fuel tank is carried on a light support directly over the radiator, feed being by gravity. Power is transmitted by cone clutch and a gearset, affording but one speed forward and reverse, to the rear axle.

The operator is located well back of the rear axle, steering being by a vertical column, connected by suitable linkage to the pivoted front wheel. The cutter bar can be raised or lowered by a long lever at the operator's right, this being arranged to automatically engage a special clutch for placing the knives into and out of action. The appearance is very neat and the construction is such as to permit of easy operation.

Of the 33 cars which started in this year's tour de France, 22 were equipped with Bosch ignition.

PAIGE FOR ARMY MAN.

Detroit Maker Secures the Order in Competition with Five Other Concerns.

Whenever a motor car manufacturer is enabled to place one of his machines with the United States government, he feels that he is entitled to congratulations for himself and his product. Therefore, the Paige-Detroit Motor Car Company, Detroit, takes pardonable pride in announcing that it has just delivered a model 36 Page roadster, to Lieut. Kenney, Chicago, recruiting officer for the United States army in that district.

Six cars competed for the sale. The complete specifications and analysis of the materials used in these cars were sent to the Secretary of War at Washington, and the selection was made after

Amlot Combined Plow and Tractor, Indicating Novel Arrangement of Plowshare Frame.

due consideration of all the details thus supplied.

AFTER MOTORCYCLE BUSINESS.

Goodyear Company Expects to Produce 190,000 Tires of This Type in 1914.

According to S. A. Falor, manager of the motorcycle tire department of the Goodyear Tire & Rubber Company, Akron, O., that company is well squared away for the largest motorcycle tire business in its history. In the three years, 1911, 1912 and 1913, this company made and sold 250,000 tires of this type, but it expects to produce 190,000 this year alone.

Mr. Falor adds that the company has added 50 per cent. to the durability of the rubber in the tread stock, to compensate for the heavier loads which motorcycles are carrying.

WHITE SYSTEM OF MOTOR LUBRICATION.

THE White system of motor lubrication, the invention of Ernest M. White, a consulting engineer of Globe, Ariz., who is now located in Detroit, Mich., has been recently brought to the attention of automobile motor engineers, who have manifested much interest in it. The system is a construction of the crankcase internally so as to provide for a progressive feed of the lubricant to each of the big ends of the connecting rods so that the splash flowage will be uniform in every condition in which the engine is used. As the statement would indicate, this is an application of splash lubrication.

The majority of motors in use today are lubricated by a distribution of oil internally in the en-

ance, for the main, crankpin, wristpin, camshaft and timing gear bearings, the piston and cylinder walls and the valve tappets and guides, as well as the timing gear faces and the valve cams, must be oiled.

It is evident that an excess of lubricant will not be a reason for objection unless there is an accumulation in the combustion heads of the cylinders, but a volume insufficient will quickly result in damage, and the necessity of supplying the forward portion of the motor when ascending a grade and the engine is worked the hardest has impelled the combination of a mechanical feed that will insure a supply being carried to the timing gears and forward main bearing.

The splash system is primarily the dipping of the big ends of the connecting rods into pits or gutters made transversely in the web, forming the bottom of the crankcase in which oil is collected as it drains from the walls of the case. As the motor heats the fluidity of the lubricant is increased and it flows more rapidly, but the need of the engine is greater and the distribution is faster. As the volume of oil lessens the quantity available for hard or fast work is consequently diminished, and while there might have been excess for slow operation there is not sufficient for continued use at fast speed. If the source of supply is variable with the position of the engine, with reference to the grade, mechanical feed is expected to furnish oil to those parts where the least quantity is supplied. Theoretically, the rapid revolution of the connecting rods is supposed to create a mist of oil in the crank chamber, and this should be distributed by centrifugal force. It will be understood that considerable depends upon the state of the fluidity of the lubricant.

The claim is made for the White system that the volume of oil splashed from the oil pits about the engine case is the same for all motor speeds, no matter whether the motor be level or placed at an inclination of 25 degrees above or below the horizontal, which is equivalent to ascending or descending a 46 per cent. grade. It will be understood that this is a gradient that is extreme, for operation in a condition that would equal this would not be regarded as practical by any experienced motor operator.

The specific value of the system is that it insures a constant supply of oil at all times, whereas in other methods of lubrication the oil is concentrated at varying places in the pits or pools and not where the fullest supply is afforded to

Transverse Section of Motor with White Oiling System at Angle of 17 Degrees, Showing Oil in Reservoir and Crank Pits, and the Location of the Drainage Channels at the Sides.

gine, this method being regarded by most engineers as being satisfactorily efficient, and is applied because conditions generally establish its practicability. The ease of construction, simplicity and the certainty of operation are also factors that have impelled engineers to utilize this method, although some have adapted combinations which are regarded as productive of specific results.

Motor lubrication is dependent upon varying conditions and each moving part ought to be supplied a sufficient volume of oil to meet every requirement, this with reference to temperature, speed and quantity of lubricant contained in the supply, these factors being of decided import-

the scoops attached to the big ends of the connecting rods. When baffle walls or separate troughs are provided the quantity in each may vary considerably, some of the cylinders being "starved" and others flooded when the grades are extreme. Operation in such conditions may result in serious damage to a motor.

The White oiling system is shown in a sketch of a longitudinal section of a crankcase and illustrates the peculiar form of the splash troughs and the "dippers" on the connecting rods, as well as the oil level in the troughs when the motor is inclined, as when climbing a gradient equivalent to 46 per cent. This indicates the possibilities in circumstances that would probably never be reached. This sketch assumes that the surface is level transversely, but the other shows a transverse section and the surface of the oil in the pits with the motor inclined 17 degrees. From these two one will gain a very clear idea of the manner in which the oil is concentrated and retained, where it can always be utilized.

The oil may be contained in any convenient form of reservoir attached to hose of crankcase, from which it may be drawn by any suitable type of pump, fed through a sight feed if desired, and then delivered, either over the timing gears or to the splash trough for the front or No. 1 cylinder. As will be noted, on the side walls of the crankcase are grooves or channels that are sufficiently inclined to insure a flow of the oil drained from the walls toward the rear of each of the oil pits or troughs, but draining into the trough behind.

Examining the second sketch one will see that the oil carried forward by the pump is drained into No. 1 trough. Here it is splashed transversely across the case and distributed centrifugally, and after lubricating this section and the working parts the drainage is collected in the side channels and carried to No. 2 trough. The operation is repeated to the last trough, and the drainage from this is into the oil reservoir. The pump is adjusted to give a stated quantity each revolution, and thus the drainage is collected progressively and an equal volume of oil supplied each trough, no matter what the number of cylinders. Each trough is abundantly provided for, and no

one will receive more than another, for the movement of the oil is specifically directed. The flow of oil from the front splash trough to the rear of the motors is illustrated, the oil being represented by what might be mistaken for wicks.

The inventor claims that besides definite efficiency the simplicity and low cost are material factors. When installed when a motor is built the cost is no greater than that of the simplest system, using a pump or the flywheel to lift the oil from the oil sump to the splash troughs. The uniform distribution of lubricants under all operating conditions is maintained to be especially desirable for practically every form of motor used for motor vehicles, motor yacht or aeronautical purposes. The inventor maintains that the sys-

Longitudinal Section of Motor with White Oiling System at Angle of 25 Degrees, Showing Form of Crank Pits and Their Retention of Oil, the Dotted Line Indicating Bottom of Drainage Channels.

tem has been thoroughly tested on long and heavy grades in the mountains of Arizona, being installed in four and six-cylinder motors of different makes, and that the efficiency and uniformity of the lubrication gave marked increase of mileage to the gallon of fuel, no smoke was exhausted and the motors ran cool and had as much power at the top of a long grade as when the start was made.

The annual Springfield automobile show and industrial exposition will be held in the Auditorium, Springfield, Mass., March 28-April 7, at which all the local dealers will be represented.

GIBAUD MAGNETO HAS NOVEL FEATURES.

A MAGNETO which presents interesting features, in that its maker has departed from conventional practise, is the Gibaud, a French design, which is now being made in England under patent rights. The instrument is very compact and follows usual practise in general design, consisting as it does of a laminated

Fig. 1—Gibaud Contact Breaker.

ated H section armature and horseshoe magnets of the permanent type. It is a true high-tension magneto, the armature carrying a coarse and a fine winding.

The contact breaker or mechanism utilized for interrupting the primary current, and the method of obtaining the required reduction in speed between the armature shaft and the distributor are novel. By referring to Fig. 2 it will be seen that the circuit breaker mechanism, which is depicted at Fig. 1, is located inside the armature tunnel, and that the distributor is placed at the end of the armature shaft, a position generally occupied by the circuit breaker mechanism and its housing.

The contact breaker comprises a base plate to which is attached the fixed platinum contact point. The other point follows general practise, in that it is removable, being mounted on a rocker arm having a fibre block. The entire construction is attached to the end flange of the armature and revolves with it. The stationary cam, which causes the points to separate, is mounted on the end plate casing in such manner that it can be partially rotated to obtain the usual advance and retard features.

Accessibility and ease of adjustment of the interrupter are features. By displacing a cover plate, shown at Fig. 2, the breaker mechanism is visible, and by releasing a spring catch, the breaker and base plate will practically remove themselves. This makes it a simple matter to clean and adjust the contact points.

The distributor is very compact. It resembles somewhat the type utilized by the maker of the Bosch magnetos, and the segments are imbedded in non-conducting material. Instead of employing a gear on the armature shaft and meshing it with a larger gear on the distributor, bevel gears are utilized, somewhat in the same

manner as a differential on a motor car. A crown bevel gear is mounted on the extremity of the armature shaft, and a similar member is immovably fitted to the casing of the magneto. Between these gears and meshed with them, is a pinion gear, carried as it were on a radial shaft, one end of which encircles the armature shaft, and is supported by the latter through a ball bearing.

The reduction necessary is obtained by the pinion gear being carried around the armature spindle 180 degrees to a complete revolution of the armature shaft, or, in other words, the small member makes one revolution to two of the armature shaft, thereby obtaining the desired reduction.

The distributor is displaced easily when desired by springing out two springs as shown. A construction resembling that utilized on the Bosch ZR types of magnetos.

FINDS BUSINESS GOOD.

Miller Tire Official Predicts Best Year of Industry's History in the South.

F. C. Millhof, sales manager for the Miller Rubber Company, Akron, O., maker of Miller tires, recently returned to the factory after an extensive trip through the South, visiting Atlanta, Savannah, Jacksonville and Tampa in the East, and points as far west as Little Rock, Ark. He reports that optimistic conditions prevail throughout the entire district, and predicts that 1914 will show the biggest year of the industry's history in the South. He also found that the Miller tire is well known in that section.

F. R. A. M. ELECTRIC FRONT DRIVE TRUCK.

Constructional Details of Interesting French Machine, One Hundred of Which Have Been Purchased by Paris Municipal Officials for Varying Service.

BECAUSE of the increasing use of electric vehicles abroad, particularly by municipal authorities, etc., some consideration of the F. R. A. M. five-ton model, built in the De Dion-Bouton works, Paris, France, will prove of interest. This is especially true, since within the past few weeks the maker has invaded Great Britain with this machine, and it is not improbable that some effort will be made to introduce it in America.

Accompanying illustrations present some of the details of construction, particularly the substantial lines of the chassis. Of course, following the practise generally obtaining abroad, the bodies are built to specifications, and that shown herewith is utilized by the municipal authorities

and recoil springs, each motor driving one forward wheel, independently of the other, through double reduction spur gearing to gear wheels bolted to the inside of the road wheels. This construction is brought out partially in one of the smaller illustrations, although, since the whole arrangement is suitably enclosed, it is impossible to note the details employed.

The battery is of 44 cells carried in trays, six of which are located on the fore carriage directly above the motors, fully protected by a removable hood, which also provides for easy access to them whenever necessity requires. It will be understood that this fore carriage is fitted on a pivot so that it is possible to swing the road wheels

Five-Ton F. R. A. M. Electric Truck, Made in De Dion-Bouton Factory and Fitted with Specially Designed Body, in Service with Paris Municipal Authorities.

in Paris for the collection of refuse—street sweepings, etc. It is understood that 100 of these vehicles have been purchased by the officials of that city for various purposes.

It may be added that the type was first produced in the three-ton capacity, and vehicles of this weight have been in service in France for a matter of a year. The newer five-ton model is identical in design, although, of course, the construction differs, in that the components are made somewhat stronger to take care of the additional load.

Two seven-horsepower compound wound motors are suspended from the fore carriage by coil

in such manner that either or both sides, or ends, of the hood may be raised at will. This is still further indicated by the illustration, which shows one portion of the hood removed, and the cells exposed. The remainder of the battery, consisting of three trays, is placed under the driver's seat, where it is equally as accessible.

This battery is rated at 350 ampere-hours, with a mileage of from 25 to 30. It is stated, however, that when the vehicle is going down grade it is possible to make use of the motors as braking dynamos, generating current which is returned to the battery as an extra charge. The amount of this extra charge is dependent, of

course, upon the character of the locality in which the vehicle is worked.

Five forward speeds and one reverse are pro-

Front View of Five-Ton F. R. A. M. Electric Truck, Showing Battery Trays Exposed for Removal—Note Enclosed Motors Driving Front Wheels.

vided, and these are controlled by a vertical lever located at the driver's left. The average maximum speed for which the machine is geared is about 7.5 miles an hour.

Steering is by a combination of worm and bevel gear, and the vehicle, which has a wheel-base of 168 inches, has a turning circle of 33 feet. An interesting feature in this connection is that, when turning sharply, contacts automatically put more cells into circuit with one motor than the other, thereby speeding up the outer wheel.

The maker of the F. R. A. M. has taken into consideration the fact that a vehicle of this type should be available for a wide variety of service, and suitable provision has been made for fitting detachable bodies. The body shown has, as has been stated, been used in Paris for the collection and disposal of refuse. This has been designed with the idea of preventing dust and litter from being blown about the street, and the various compartments are provided with separate covers, two opening from one side and two from the other. It may be added that the division of the sliding cover is four feet eight inches from the ground, facilitating loading.

These compartments open into each other, virtually making but one, so that the vehicle is readily dumped at the rear. One of the smaller illustrations presents an attendant in the act of dumping a load, this being accomplished by means of a hand operated winch, which draws the bottom end of a steel arm on either side along a curved track, forcing the forward end of the body to a suitable angle for discharging the load.

A winch is provided on each side, so that two men may expedite the work.

It should be added that the chassis is fitted with dual tires, both front and rear. The weight of the body shown is approximately two tons. Attention also may be drawn to the fact that with the provision for easy access to the battery trays, it is held to be possible to make a complete change of battery in 10 minutes. This is considered a decided advantage in municipal work, since it has frequently been the case in Paris, that a vehicle has been required to cover some 20 or 25 miles in the morning, returning to the garage at noon for a change of battery and performing a like service in the afternoon.

AUTOMOBILES EXCLUSIVELY.

Horses Are Entirely Eliminated at Panama-Pacific Exposition Grounds.

For the first time in the history of international expositions, or world's fairs, motor trucks are being used to haul the material used in construction work in connection with the preparations for the Panama-Pacific exposition in San Francisco, Cal., in 1915. A horse would prove a decided curiosity on the grounds, as in every instance automobiles are being utilized.

Incidentally, it may be remarked that this work is proving of decided importance as an object lesson to San Francisco business men. Few cities of the country have such steep hills, and yet the motor trucks have been able to negotiate

Indicating Method of Operating Dumping Mechanism on F. R. A. M. Machine Utilized by Paris Officials.

them without difficulty. The rapidity with which the preparation work has progressed is held to be due very largely to their use.

INSURANCE AGAINST THEFT.

Gasolock Controls Fuel Supply, Preventing Operation Except by Holder of Key.

In spite of the severe penalties prescribed for the use of cars by others than those having the right to operate them, the list of machines reported stolen is rapidly increasing, and a large number of cars have practically disappeared, so clever are the bands of organized automobile thieves. As a result many owners are now carrying insurance who formerly did not deem the precaution necessary.

The Headlight Support Company, Dime Bank building, Detroit, is manufacturing the Gasolock, which is held to eliminate the need of insurance, in that it shuts off and locks the fuel supply, one of the most practical methods of locking a machine. One of the qualities of the device is that it is easily and quickly operated from the seat. By turning a thumb button the supply of gasoline to the carburetor is shut off and locked until the owner of the key releases the mechanism by means of a Yale key, no two of which are alike.

The Gasolock presents several other practical features. It prevents waste of fuel through a flooding carburetor, and in the event of the latter catching fire because of a backfire, the supply of fuel can instantly be shut off, preventing a serious loss. As the thumb button is convenient the fuel supply may be closed and locked, and without having to stoop and search for petcocks, etc.

The Gasolock is not only neat and compact, but is nicely finished. Nickel and brass are standard and its installation is a simple matter. Two Yale keys are supplied with each lock and the third is kept by the company, filed away with the owner's number, so that in case both keys are lost a wire or letter will bring the extra key without charge and by special delivery.

The Gasolock is not only guaranteed for life, but it can be installed on any car and used over again. It is moderately priced and its cost will pay for the usual insurance. It also is adaptable to motor boats, motorcycles and cyclecars.

FOURTEEN ENTRIES NOW.

Expected That There Will Be at Least 30 Starters in This Year's 500-Mile Race.

Although there are but 14 actual entries for the fourth annual international sweepstakes 500-

mile race on the Indianapolis speedway, Memorial Day, it is expected that not less than 30 cars will start. A number of other machines are known to be certain entrants.

The list reads as follows: Stutz, Anderson; Stutz, Cooper; Burman, Burman; Burman, unknown; Gray Fox, Wilcox; Bullet, Keene; Peugeot, Goux; Peugeot, Boillot; Sunbeam, Chasagne; Delage, Guyot; Excelsior, Christiaens; Peugeot, Duray; King, Klein; Delage, Thomas.

USES ELECTRIC ROADSTER.

Well Known Detroit Manufacturer Thinks Others Will Soon Follow His Example.

An accompanying illustration presents W. C. Anderson, president of the Anderson Electric Car Company, Detroit, maker of the Detroit electric line of pleasure cars and trucks, and the De-

W. C. Anderson, President, Anderson Electric Car Company, and His Detroit Electric Roadster.

troit electric roadster, which he drives every day of the year, regardless of weather conditions. Mr. Anderson is often spoken of as "The youngest man about the factory", and he declares that the secret lies in his policy of: "Don't worry, eat simple food and keep out of doors as much as possible".

Mr. Anderson drives the car himself, for, as he puts it, he has no time to wait for a chauffeur to get ready to start. Neither has he any patience with the housed-up business man who misses an opportunity for a breath of fresh air en route to and from his office, by allowing himself to be driven about in a closed car. He prophesies that when the pleasure and healthful recreation, as well as the flexibility of the electric roadster, is better understood by the average business man, the electric car will predominate for his city requirements.

MECHANICAL NOTES FOR OWNERS.

Operation of Briggs Magneto and Wiring Plan for Four-Cylinder Motors---Home Made Clutch Pedal Pad---Timing Overhead Valves---Care of Batteries.

OWNERS who care for their machines should have at least a working knowledge of the operation of the ignition system with

Briggs Model A Magneto.

which the car is equipped and should keep in the garage or on the vehicle a copy of the wiring plan, so that in the event of trouble corrections may be made. This applies particular-

ly to the low-tension type of magneto which utilizes a transformer or step-up coil for building up the primary current generated by the instrument, and which employs batteries for starting or for an auxiliary source of current supply.

The Briggs magneto, made by the Briggs Magneto Company, Elkhart, Ind., which is standard equipment on 1913 and 1914 cars, is a low-tension instrument, in that the armature core has a single winding of coarse wire. The transformer coil is carried separately on the dash under the hood, the switch being located on the driver's side.

In an accompanying illustration is presented the wiring plan of the magneto and it will be noted that there are five high-tension leads with a four-cylinder instrument, these including four to the plugs and one conveying the built-up current from the coil to the distributor. The terminal of the last named is the centre member just forward of the others.

The battery current is not grounded. Both the positive and negative leads are attached to the upper right hand terminals marked "bat" in the drawing. The transformed current is led from the extreme left hand upper terminal to the distributor and it is important that the connections be clean and tight, as

high-tension current flows through this wire irrespective of whether the source of current supply is the cells or the magneto.

The balance of the wiring plan comprises three primary leads, and as these are marked 1, 2 and 3 in the drawing, it should be a simple matter to memorize their order. The Briggs instrument is automatically lubricated, the maker stating that the supply is sufficient for 15,000 miles of service.

CLUTCH PEDAL PAD.

The manufacturer of the modern machine has refined many details so as to contribute to ease of operation and provide a large factor of safety. Among these is the clutch pedal. Formerly, little attention was given these members other than corrugating the pedal proper. After considerable service the surface becomes smooth, sometimes resulting in the foot slipping when quickly applied.

The following suggestion for fitting the clutch pedal with friction material is made by a reader and the plan could be utilized with the brake member: Take an old pair of rubber soled tennis shoes, not too badly worn, and cut off the heels with their uppers. Punch some holes in

Wiring Diagram of Four-Cylinder Briggs Magneto, a Low-Tension Instrument Using Dash Type Transformer Coil.

the cloth section as shown at A in an accompanying illustration, also a slot to permit of the material being laced snugly around the pedal. By

Home Made Clutch Pedal Pad.

utilizing a stout lacing the material can be so secured as to make a pad as shown at B.

The contributor states that while the job is not as

attractive as the marketed pads, it is very serviceable, costs nothing to make and is easily fitted. He also suggests the possibility of securing a tennis shoe that is in very good condition.

TIMING OVERHEAD VALVES.

The majority of owners prefer to rely upon the expert when it becomes necessary to retime the valves of a motor, but there are a large number of motorists who are very proficient in the work and for their benefit the following discussion of timing valves of the overhead or rocker type, contributed by a repairman, is presented:

It should be borne in mind that the opening and closing of the various valves has much to do with the balancing of an engine, and that often excessive vibration is due to a variance in the opening and closing points of the valves.

The method adopted includes disassembling the motor and utilizing the crankshaft, flywheel and upper half of the crankcase. The last named is placed on a level surface and sufficiently high to clear the flywheel, as shown in an accompanying illustration. The crankshaft is then rotated until the crankthrows of the first and fourth cylinders are exactly on top dead centre. This position is obtained by means of a square held to the side of the crank web and a spirit level placed on the top of the blade. Having obtained this position, a pointer, constructed of a piece of tin, is placed on the centre of the crankcase as shown, and so located that its point will overlap the flywheel. A line is then scribed on the flywheel, which indicates top dead centre.

The flywheel is then rotated a half turn, or until the throws on the second and third cylinders are on top, and the exact vertical position is obtained by means of the square and the level. The flywheel is also marked. The cylinders are next replaced and other parts of the motor re-assembled.

The crankshaft is then rotated until the exhaust valve of the No. 1 cylinder closes. This should take place shortly after dead centre. A chalk mark is then placed on the flywheel opposite the pointer, and the flywheel turned until the No. 4 exhaust closes, when the flywheel should again be marked where the pointer overlaps.

Any difference between the timing of the No. 1 and No. 4 markings, with relation to the pointer, can be altered by turning the camshaft backward or forward one or two teeth as required. The No. 1 and No. 4 intake valves are treated in a similar manner, and with a little adjustment of the tappets, the intake valves referred to will fall in with the correct timing of the motor. The position of the valves should be taken both open and closed.

DRY CELLS AND STARTING.

The number of motorists who do not use their machines during the winter months is steadily decreasing. Those who have stored their cars, and who are not familiar with batteries, either the storage or the dry cell, will do well to give these members attention before attempting to start the motor for the first time in the spring.

Dry cells deteriorate with age. This applies to those which were practically new when the car was put away, and it is rare that the average make of dry cells will show sufficient amperage to warrant their use after they have been standing for two or three months. It is possible that readings with an ammeter will show eight or 10 amperes, and, while it might be possible to start the engine on these, it is only a

Timing Motor with Overhead or Rocker Type Valves by Utilizing Crankthrows.

question of time when the output of the batteries would be so reduced that starting troubles would be experienced.

In placing the machine in commission it is best to throw away the old cells even if they show 10 amperes, for it should be borne in mind that with the present grade of fuel a good, hot spark is more essential than when higher test gasoline was marketed.

If it be found that one or two of the cells test, say 12 amperes for example, it is not good practice to retain these and add four new ones in an endeavor to economize. It is of no use to cut in new cells with old ones in series as the resistance of the latter is very high. If three old cells were to be added to three new ones, the latter would have to work through the high resistance of the dried up elements of the old ones. This explains why it is sometimes possible for the expert to take an apparently exhausted set of cells and by throwing out one or two obtain sufficient current to operate the car temporarily.

In wiring a set of new cells, either in series or multiple series, the terminals should be set up snugly, and, after the car has been in service a short time, the terminals should be gone over and retightened. Much of the trouble in starting is due to a loose connection which sets up a high resistance to the passage of current from the other batteries. In installing the new cells, make sure that none of the wires leading from the battery box come in contact with any sharp metal corners. When the leads are in proximity to metal, tape the wire. Cells should be so installed that they cannot bounce around in the container. It is a simple matter to pack them with paper, and in placing them in the box locate them so that terminals will not be in contact or near each other. In testing cells the ammeter should be kept in the circuit long enough to obtain a true reading; that is, until the indicating hand comes to a stop.

If the storage battery has been properly cared for, and in accordance to the instructions of the maker, all that it will need will be recharging, and this is best done by the battery expert, who will determine whether or not it requires a long, slow charge. The writer recommends taking the battery to the expert, as it will insure satisfactory service after replacing it in the machine. It is also possible that it may need some slight attention that would naturally be overlooked by the owner.

H. J. Galvin, who has been with the Remy Electric Company, Anderson, Ind., for a number of years, and is well known to the trade in the East, has been appointed manager of the San Francisco branch of the company.

AS TO PRICE CUTTING.

Detroit Electric Official Discusses the Subject from Viewpoint of His Company.

Recently the Anderson Electric Car Company, Detroit, maker of Detroit electric machines, created unusual interest by advertising in the Chicago newspapers that it would pay \$1000 in cash to anyone who could purchase or cause to be purchased from the company in that city a new 1914 Detroit electric at any time during the 1914 season at less than the regular, established prices. In commenting upon the situation, D. E. Whipple, an official of the company, states that this was merely a public announcement of a policy long followed by this concern. He adds:

People are gradually coming to realize that they do not gain anything by buying an article which has been purposely given a high list price in order to permit the dealer to "throw off" something to the purchaser. In determining the selling price of an automobile, or any other article, the manufacturer first arrives at his manufacturing cost, and that cost is absolutely determined by quality, volume and manufacturing facilities. When that cost has been determined, the selling price is then fixed by adding to the cost such profit as the manufacturer expects to realize.

The original selling price of an automobile or other article that is sold at a discount must of necessity have been purposely fixed high in order to permit of price cutting. The buyer of such an article may be led to believe that the cut or discount is strictly personal and confidential, but if he stops to think he will ask himself: "Why should I be allowed to buy this thing cheaper than anyone else?" And then will come the questions: "Am I getting the lowest price, after all?" "How do I know that someone else is not getting an even larger discount than I?"

Price cutting is coming to be recognized as one of the worst evils in business. It is not only bad for the manufacturers and dealers—it is even worse for the purchaser, for the manufacturer who will cut the price is not unlikely to shade quality to correspond.

The only sound way of doing business is to have a fair, honest price and stick to it. That is the practice in all the old established lines of business. Some day it will be the universal rule in the automobile business. The only reason that the evil of price cutting has ever crept into the motor car industry is because it is a new business and has to pass through certain evolutionary stages. But the stronger concerns, the ones whose methods and products can be depended upon, are taking a definite stand in favor of price maintenance—and wise purchasers realize that such a policy is of the greatest protection and benefit to them.

Vulcan Touring Car Sells for \$850—In the two-page advertisement of the Vulcan Manufacturing Company, Painesville, O., appearing in the March 10 issue of *The Automobile Journal*, the caption under the cut of the Vulcan touring car inadvertently omitted. This should have read: read: "Vulcan touring car, five-passenger, 115-inch wheelbase, electric lights, \$850".

The first run of the Cyclecar Club of New England, formed during the recent Boston automobile show, will be held Memorial Day.

SPECIALLY DESIGNED MUNICIPAL WAGONS.

Indicating the Manner in Which Department Officials and Motor Car Manufacturers Have Co-Operated in an Endeavor to Meet the Needs of Public Service.

PERHAPS no one field offers greater possibilities for the maker of motor vehicles than that which may be termed municipal service. Obviously, in its broadest sense this term must be applied to the transportation needs of any and every department, but, as generally applied, it has particular reference to fire and police apparatus. Insofar as the needs of any department, such as that of streets for example, are identical with those of business men engaged in similar work, the trucks available for this purpose cannot well be classified as municipal service vehicles. A truck equipped with dumping body engaged in carting grading material for the city is no different from a truck of the same make fitted with the same type of body in

the space allotted in this instance, and it is significant that fire department officials have co-operated most exhaustively with automobile manufacturers in an effort to secure greater efficiency. This applies particularly to the gasoline pumping engine.

Fire and Police Work.

The matter of first cost occupies the largest interest on the part of municipal authorities and the tax payers, since it can readily be demonstrated that motor equipment is more economical and many times more efficient than horses. It may be conceded that the automobile is a source of expense only when in use; it eats nothing while standing in the station. Less room is required for storage; consequently, it costs less

Adams Truck Chassis to Which Members of Central Fire Department in Findlay, O., Fitted Equipment Taken from Apparatus Already Owned by the City.

service with a contractor. There are, however, a much larger number of specially designed motor vehicles supplied for use in public work of one kind and another, than is generally supposed by those who are not well informed, and it will be the object of this discussion to call some of them briefly to mind.

Within the past few years, the fire departments of larger cities have been completely motorized, and even the smaller cities and towns have acquired automobile apparatus, so that, in itself, the motor equipped fire wagon is no longer a novelty. The various types of such vehicles produced by the industry would afford opportunity for a single discussion occupying many times

for land and building. The motorized engine house is cleaner and more sanitary for the men. But, in many cases, the city already owns horses and apparatus, and the land and buildings. To the small city or town, therefore, the purchase of a machine often involves the more than the first cost of vehicle.

This feature has been given due consideration by the manufacturer, and many are offering means for overcoming the difficulties presented. On this page is illustrated a combination chemical and hose wagon built by the members of the central fire department in Findlay, O. It differs somewhat from standard design, it is true, but it offers an important suggestion to the small

Two Knox-Martin Tractors Which Solved the Problem of Saving Existing Apparatus for the Fire Department of Mount Vernon, N. Y.

community which may desire the advantages of of automobile apparatus at limited cost. The chassis is that of an Adams 1.5-ton truck, made by the Adams Bros Company of Findlay. The equipment—body, chemical tank, hose, ladders, etc.—was taken from a piece of apparatus already owned by the city.

Still another suggestion for the municipality which does not care to dispose of its present equipment, yet desires the efficiency of motorized apparatus, is to be found in the illustration showing the solution adopted by the fire department in Mount Vernon, N. Y. In this instance, the city owned two heavy pieces, one a steam fire engine and the other a large hook and ladder truck, and purchased two Knox-Martin tractors, made by the Knox Automobile Company, Springfield, Mass. The saving in maintenance cost as a result of the change from horses has averaged about \$60 a month, or a little better than \$2 a day.

The need for prompt and efficient service is quite as marked in the police department. With particular reference to the patrol wagon, attention may be drawn to the vehicle shown herewith, recently supplied to police of New York City by

the Willys-Overland Company, Toledo, O. The chassis is that of a Willys Utility 1500-pound wagon, fitted with a special screen side body, providing room for 12 persons inside and two on the driver's seat, the only change in the standard model being an increase in the wheelbase, from 120 to 144 inches. Not all patrol wagons are fitted with a screen side body,

and it will be noted that this one is supplied with curtains, making it possible to entirely shield the occupants from view. The Willys-Overland Company has decided to specialize on this type of vehicle, and the initial order for the New York department was 25 machines. Of course other companies are specializing in this work, this reference being noted only as an example.

Saving Human Life.

Most smaller cities prefer a combination patrol wagon and ambulance. Worcester, Mass., has three, besides the one shown herewith. This is a White vehicle, made by the White Company, Cleveland, O. It differs from the combination machines, which also are of the same make, only in the absence of the windows at the side. This is strictly a public service vehicle, and as such may not be expected to possess the same ornate

Mine Rescue Wagon Fitted to White Chassis Recently Installed at Pittsburg, Penn., by United States Bureau of Mines.

One of the 25 Patrol Wagons Recently Delivered to the New York City Police Department by the Willys-Overland Company.

appearance that would be found in a privately owned hospital ambulance, however, the main features of economy and efficiency are presented. This particular machine has been in service over two years and during that time has been instrumental in saving hundreds of people from serious results or loss of life, through the ability of the police department to rush them to hospitals or place them in charge of physicians in time of accident.

Mine Rescue Wagon.

The saving of human life is a factor that cannot, of course, be expressed in dollars and cents. The item of economy enters very little into the equation in that instance, while efficiency is of the utmost importance. The United States government is setting a valuable example to cities and towns in this respect, through its bureau of mines, which has stationed the special miner's wagon illustrated, also a White chassis, at Pittsburg, Penn. This step has been taken in an effort to interest municipalities, and mine owners, in such districts, in providing similar service.

The body is constructed with many compartments for

carrying the tools, instruments and utilities which might be used in the event of a mine explosion, etc., Beneath the driver's seat are two Draeger reviving outfits, and under the body on a sub-frame are six oxygen tanks. The oxygen pump is at the left side and is driven by the motor. Other paraphernalia carried are: Tent, 22 feet of rope, three miner's picks, three miner's shovels, a four-pound sledge, two axes, saws, hose couplings, reducers, spanners, 200 feet of half-inch rope, lifeline reel, telephone system, bits, braces, chisels, hacksaws, snatch blocks, mine lanterns, two first aid boxes, 50 regenerators, two pulmotors, and, in fact, everything that might by any means be needed in case of a mine accident, even to a caged bird, which is taken into the mine to detect the presence of poisonous gases. Vehicles of this type, although somewhat differently equipped, are used quite extensively abroad, particularly in the mining districts of Great Britain.

Street Department Work.

Of course the street department has use for numerous types of vehicles. Most of these cannot be regarded as specially designed, but the

White Ambulance in Service with the Police Department of Worcester, Mass., for the Past Two Years.

KisselKar Combination Street Sprinkler and Flushing Machine.

Kissel Motor Car Company, Hartford, Wis., has brought out the combined street sprinkler and flusher presented herewith. This is mounted on the regulation KisselKar three-ton truck chassis, to which is fitted a 1000-gallon galvanized steel tank. Pressure is produced by taking the water by gravity from the bottom of the tank into a two-stage centrifugal pump direct connected with the motor. It is then forced into distributing pipes and out through adjustable nozzles for flushing, and through two pipes to sprinkling attachments of the vehicle type.

As a result of the growing tendency for using oil on streets, several types of vehicles designed for such service have made their appearance. One of these is shown elsewhere in this issue, in connection with the review of the Boston motor truck show. Motor street sweepers also are used quite extensively abroad, and in this country, in some instances.

In another place, attention is drawn to a new type of body utilized in Paris for carting street sweepings. This serves to call to mind the garbage disposal wagons in service both in this country and abroad. In many instances this involves the use

of a specially constructed body similar to that shown on the F. R. A. M. truck, to which reference is made, but in others the Knox-Martin tractor has been utilized to decided advantage in hauling loaded horse drawn wagons of the type already in service. Under this latter plan, horses are used in collecting the garbage and in delivering it to some central point, from which point the tractor is called upon to transport the loaded vehicles to the disposal plant.

In the Sewer Department.

Special mention may be made of the sewer department in considering the equipment installed by the city officials of Pawtucket, R. I., for cleaning catch basins, and shown herewith. The chassis is that of a Standard three-ton truck, made by the Standard Motor Truck Company, Detroit, and the body is from the factory of the Monahan Vehicle Company, Providence, R. I.

The particular feature of the outfit is the arrangement for hoisting and dumping the refuse, which was devised by James Nesbit, an employee of the department. Directly back of the driver's seat is a two horsepower single-cylinder auxiliary engine, geared to a hoisting drum, from which a cable is run through the centre of the crane and over pulleys on the arm. This engine draws its fuel supply from the same source as the regular motor which propels the truck, and the exhaust communicates with the muffler. The water circulation is connected with the radiator, so that the two engines utilize practically the same system. At the front of the body is an hydraulic hoist for dumping the load, this comprising a long cylinder with a piston forced up-

Standard Truck Chassis, Equipped with Special Apparatus, in Service with Sewer Department in Pawtucket, R. I.

ward by oil from a gear pump, which is driven by a connection in the transmission case. This machine is doing the work of six horse carts and 12 men in cleaning out the catch basins of the city.

The subject has been by no means exhausted, although the space has. It would prove of interest to catalogue the long list of products of various makers available for special work in municipalities, each of which has been designed with special reference to economy and efficiency. The only attempt that could be made herein was that of citing a few of the many instances in which the industry has sought to meet the need for public service vehicles calculated to reduce the annual budget, and meet the approval of the tax payers, as well as the city officials.

MOTOR TRUCKS OF AMERICA.

B. F. Goodrich Company has Compiled an Exceedingly Valuable Reference Work.

Prospective purchasers of motor trucks and business wagons will appreciate a copy of "Motor Trucks of America", volume II, which has just been issued by the B. F. Goodrich Company, Akron, O. The work is one of the most complete that has been compiled by any source, presenting detailed specifications and illustrations of some 100 makes of vehicles produced in this country, all of which are fitted with Goodrich wireless truck tires, made by this company, either as standard or optional equipment.

In addition to the descriptive matter respecting the trucks listed, the book, which contains 112 pages, presents timely and valuable articles concerning "Efficiency in Buying and Operating Motor Trucks", "Efficiency Guide for Buying Commercial Motor Cars", etc. Copies of the work may be secured upon application to the company at the factory or any of its branches, and those who are contemplating the purchase of such vehicles would do well to make early application for a copy.

VEEDOL IS A LUBRICANT.

A High Grade Motor Oil Made from Pennsylvania Petroleum Crude.

The Platt & Washburn Company, 7 Broadway, New York City, is marketing Veedol, a high grade motor oil, made from Pennsylvania petroleum crude, and particularly adaptable to pleasure cars, commercial vehicles, motorcycles

and internal combustion engines generally. The company was incorporated in 1885, and has had more than 30 years' experience in the production of all kinds of lubricants.

Veedol is the result of practical research in shop and laboratory, and it is maintained that tests have demonstrated that it will burn up cleanly and is remarkably free from carbon. The qualities emphasized are efficiency and economy. The company has an attractive agency proposition and the trade is invited to write for details.

SNOW AND MERCER TESTERS.

Recent Jersey Blizzard Proves a Boon to Men Employed at Trenton Factory.

It may be that, as a general thing, heavy snow storms are not welcomed by most of those engaged in the automobile business, and par-

Mercer Tester Breaking Trenton Roads After Recent Jersey Blizzard.

ticularly at the factories. But this does not apply to the testing department of the Mercer Automobile Company, Trenton, N. J., as is amply indicated by the accompanying illustration.

When the recent blizzard reached New Jersey most of those employed at the Mercer factory were somewhat inconvenienced, due to the inability of traffic to overcome the unusual conditions. Mercer testers, however, set out almost immediately to break the roads in the vicinity of the factory.

Work of this kind provides a wonderful test for the machines, and the men assigned to this duty found much greater enjoyment in bucking through a good sized snow bank than in driving their cars over ordinary roads. It may be added that the cars found little difficulty in surmounting obstacles that kept ordinary traffic within doors for a time shortly after the storm abated.

IMPROVED ROADS AND MOTORING LAWS.

Attempt to Secure Uniform Legislation Appears to Be Doomed to Failure—New Jersey Solons Will Repeal Statute Passed in 1787—Indiana to Study Highways.

UNLESS published reports are entirely misleading, it would appear that the harmony anticipated as the result of a conference between commissions representing several of the eastern states in an effort to formulate a uniform motoring law was even further than ever from realization. According to information from Albany, the New York commission reported the bill prepared by the conference, but recommended that it be not approved, substituting two entirely new bills, which, if passed, would give New York a motoring law differing in many respects from that of any other state.

One of these bills provides for the repeal of the so-called Callan law, and, instead, owners would be required to pay a single registration fee of \$2 to the state and the present exemption from taxation of the machines as personal property would be stricken out. The other prescribes rules of the road for all forms of traffic. In addition to fees, the first bill would prohibit an intoxicated person from driving, and there is a general provision that violation of the act is a misdemeanor punishable by a fine of not more than \$500 or one year in prison, or both.

MORE NEW YORK BILLS.

One Provides for Universal Lighting and Another for State Traffic Board.

Patterned largely after the law in force in Massachusetts for the past two years, a bill has been introduced in the legislature of New York State providing for lights on all vehicles using the highways during the hours of darkness. Like the Massachusetts statute, the bill makes exception of streets or highways on which street lights are maintained at not more than 500 feet apart. A penalty of \$5 is provided for each violation.

Another new bill introduced in this legislature authorizes the governor to appoint a state traffic commission to regulate motor vehicles. This is to consist of three members at an annual salary of \$5000 each. First class cities are to name one traffic commissioner at a like salary, and second and third class cities may do so when authorized by the commission, these local commissioners to have charge of the traffic squads. The bill also provides for registration fees for

motor vehicles, at \$5 for those of 1000 pounds or less, with \$5 for each additional 1000 pounds. The license fee for chauffeurs is \$2.

The bill providing for licensing all drivers of automobiles was killed in committee.

TO REPEAL ANCIENT LAW.

Automobiles Have Been Violating New Jersey Statute Passed in 1787.

It appears that practically all motor vehicles using the highways of New Jersey have been violating the law. It remained, however, for a cyclecar enthusiast to discover the truth of this statement. Assemblyman Griffin has drafted a bill repealing this measure, which was passed in 1787. In the meantime there is little danger that state or local officials will take steps to enforce its provisions.

In 1787 the legislature of New Jersey made it a penal offense to drive a vehicle having a gauge of less than four feet 10 inches, measured from hub to hub, the penalty being fixed at 20 shillings. Another section of the same law forbids the sale of axles under four feet 10 inches under the same penalty. The general statutes were revised in 1868, but this law seems to have been overlooked by the committee which had the matter in charge. Most all automobiles have a tread of 56 inches, while cyclecars run all the way from 36 to 56.

REVISING INDIANA STATUTES.

Special Committee Appointed to Prepare Recommendations for Next Legislature.

Gov. Samuel M. Ralston of Indiana has appointed a special committee of 15, whose duty it will be to investigate the present road laws of the state and prepare recommendations for the next session of the legislature in January, 1915. It is not improbable that the outcome of this revision will be the creation of a state highway commission with sufficient financial backing to build and maintain roads of the most approved type.

At present the commonwealth has no control, insofar as construction and maintenance are con-

cerned, the only financial aid received from the state being derived from the annual licenses under the motor vehicle law. Repair work is done by farmers and others, who work out their road taxes. The commission will serve without pay, as there are no funds available for this purpose.

DISCUSSES ROAD EXPENDITURES.

Automobile Manufacturer Calls Attention to Essential Facts to Be Remembered.

As an indication of the spirit of co-operation between manufacturers and dealers on the one hand, and the motoring public on the other, it is significant to note that representatives of motor car concerns are giving decidedly more attention to the subject of laws and roads than heretofore. The following statement is made public by George A. Kissel, president of the Kissel Motor Car Company, Hartford, Wis., and serves to call attention to some essential facts to be borne in mind when considering the question of expending money in road work:

Whenever the subject of retrenchment in state expenditures is agitated, some thoughtless or narrow minded persons suggest that too much money is being expended for good roads, and attribute the responsibility to the demands of automobile owners. Such people do not seem to take into account the fact that most states collect for automobile licenses a sum far in excess of the amount applied to highway improvement.

The better the roads, the more interest there is in motoring, and every increase in the number of car owners means additional revenue to the state. That is plain enough, even though we disregard the manifold benefactions to the community through the development of the automobile.

The automobile has unquestionably emphasized the necessity for better roads—I say necessity because the automobile is not a mere plaything, but a profitable utility of the utmost importance. Thousands of cars are driven by commercial travellers, by physicians, by farmers, by countless others in the pursuit of their business. It enables the drummer to cover more territory, the doctor to reach more patients more quickly, and conserves the farmer's valuable time by bringing his markets nearer to him.

The automobile has increased the value of real estate enormously. By its conservation of time it has made accomplishments possible that were never dreamed of before its advent.

Thus, no man who thinks twice will begrudge the advantage gained by the automobile through extension of the system of state highways. There is no movement in this country that does more credit to the foresight and intelligence of the people than the nation wide interest in good roads. It is an investment, not an expense, and an investment that is paying, and will continue to pay, handsome dividends in both health and wealth.

SCOUTING PARTY BUSY.

Southern State and County Officials Welcome Government Engineers on Trip.

Reports forwarded from the headquarters of the American Highway Association, respecting the government scouting party which is on its

way from Washington, D. C., to Atlanta, Ga., to inspect the roads on which it is proposed to inaugurate a system of scientific government management, indicates that the state and county officials throughout the southern states crossed are welcoming the engineers with wide open arms, so to speak. It will be remembered that this association is receiving the co-operation of the United States office of public roads in an experiment which has for its object the construction and maintenance of a through highway along lines advised by the government engineers.

The details of the plan have not been worked out as yet, but the present trip is largely for the purpose of viewing the roads in question and discussing harmonious and uniform methods of securing the desired results. The scouting party consists of the following: Capt. P. St. J. Wilson, assistant director of the office of public roads; Leonard Tufts, chairman of the maintenance committee of the American Highway Association; George P. Coleman, state high commissioner of Virginia; Dr. Joseph Hyde Pratt, state geologist of North Carolina; Preston Belvin, president, State Automobile Association of Virginia; Col. Benneham Cameron, Stagville, N. C.; E. J. Watson, commissioner of agriculture of South Carolina; S. W. McCallie, state geologist of Georgia; George C. Scale, W. L. Spoon and D. H. Winslow, high engineers of the office of public roads.

At one time it was intended to make the start when the roads would be in better condition, but it finally was decided that it would be best for the party to see the highways when at their worst, in order to know what improvements were needed. Reports from the field indicate that conditions have been found much better than might be expected at this season of the year.

MASSACHUSETTS' REGISTRATIONS.

Over 37,000 Automobiles Received Numbers During First Three Months of 1914.

Although the first three months of the new year have not ended as yet, the Massachusetts highway commission reports that over 37,000 automobiles have been registered. This is more than 50 per cent. of the total registration for 1913, which was 62,600, and it is expected that the list will reach at least 75,000 this year. Something like 800 commercial vehicles have received licenses thus far, and it is anticipated that this number will be doubled during the next few months.

MACHINERY, TOOLS, EQUIPMENT AND SUPPLIES.

JOSEPH T. Ryerson & Son, Chicago, is marketing a new machine known as the Lennox Serpentine Shear, which is held to have decided advantages in that it will cut in-and-out curves and a circle with a radius very near that of the blade itself. It is designed particularly for the straight and irregular cutting of sheets and plates.

The machine, which is shown in an accom-

Lennox Serpentine Shear.

panying illustration, has a frame of cast steel spiral construction and designed to provide sufficient clearance for material of unlimited length or width. The spiral steel frame carries all gearing and is mounted on a substantial cast iron base. All gears have teeth cut from solid metal and are provided with cast iron gear guards, protecting the workmen when they are operating the machine.

The blades are made of a high grade tool steel, are set in approximately a horizontal plane, providing a very large cutting bearing on the sheet or plate, and consequently, there is little distortion in the cutting. The upper cutter is positively driven, while the lower is mounted in an adjustable sleeve, so that its position may be varied to allow for different thicknesses of material and for redressing. In addition to this, a cam is provided so that the lower blade can be dropped enough to permit the removal of the sheets without reversing the machine. The cutters have a flush fastening to the shaft so that no nut projects to interfere with the handling of the work, and the knurled edges feed the sheet automatically into the machine. A tool steel pin is provided to take up end thrust on the lower cutter shaft.

Where a number of sheets are to be cut to the same pattern, a template may be bolted to the work and this template followed by guiding against the top cutter.

The machine is driven by means of a two-speed pulley, giving slow speed for intricate curve cutting, and high speed for straight work. The main drive shaft is extended and squared on one end so that a hand crank may be utilized if power is not available.

The shear illustrated has a capacity for cutting No. 10 gauge material and lighter, while other sizes, having capacities of No. 16 gauge, .25-inch and .375-inch material are supplied. All machines are arranged for either belt, direct motor drive or hand power. It is stated that the Lennox will reduce cutting costs fully one-half.

GIDDINGS UNDER-CUT DRILL.

The Giddings under-cut drill is marketed by the Giddings Under-Cut Drill Company, 184 Summer street, Boston, and among the features of the tool is that when utilized in conjunction with a special chuck made by the company, it will bore an under-cut hole which locks the bab-bitt metal securely and permanently to any surface.

The drills are made in standard sizes, .5, .625 and .75 inch. Special sizes are made to meet requirements. It is stated that the drills will bore a hole in five to 10 seconds, and that the best of material and workmanship are incorporated. Descriptive matter and price list will be mailed free on request.

BINKS ELECTRIC TIRE PUMP.

The Star Brass Works, 1911 Fulton street, Chicago, is manufacturing the Binks electric tire pump shown in an accompanying illustration. It is designed both for public and private garages, and efficiency is one of its features.

The equipment is most complete and includes suitable length of hose, flexible lamp cord, etc. The compressor is constructed of the best grade of iron, neatly enamelled. The cylinder has a bore of two inches and a stroke of five, and is bored and ground to exact dimensions. The piston rings are of the same material as the cylinder and as carefully finished and fitted. All parts subject to friction are equipped with spring grease cups. The valves are of special design and material and, it is stated, will require no attention.

Binks Electric Tire Pump.

The compressor is operated by a .25 horsepower 110-volt direct or alternating current motor (60 cycles), and 15 feet of lamp cord with socket is included in the equipment. Lubricant is prevented from reaching the tires by a well designed oil extractor located between the pump and the hose. The relief valve may be set to any desired pressure, preventing over inflation or the bursting of tires. The outfit is mounted on a finished, painted platform two by 12 by 30 inches, and swivelling ball bearing casters make it an easy matter to move the equipment about the garage.

The Binks electric tire pump is constructed to withstand severe service and is liberally guaranteed by a maker having 14 years' experience in the production of pumps. Price lists and descriptive matter will be supplied upon request.

VICTOR ASSORTED GASKETS.

The Victor Manufacturing & Gasket Company, Troy and 21st street, Chicago, in addition to marketing its regular line of copper asbestos gaskets, is producing them in assorted sizes

packed in boxes. Four different boxes are offered the trade, one of which is for the model T Ford car shown in an accompanying illustration.

Box No. 1 contains 12 complete sets of gaskets for the Ford car, these comprising that for the cylinder head, intake and exhaust, etc., and the company calls attention to the efficiency

Victor Assorted Gaskets.

of the gaskets, stating that it supplies the maker of the Ford car with similar members in large quantities. Box No. 2 (that illustrated) contains 200 assorted copper asbestos gaskets selected from the most popular sizes universally used, and in proper proportion for everyday repairs on all makes of cars. The assortment is augmented by 65 selective sizes of gaskets to fit all makes of spark plugs marketed.

Box No. 3 has 50 assorted gaskets constructed especially for the intake and exhaust pipes and manifolds, exhaust flanges, carburetor connections, etc. There are 25 different sizes to choose from, making the equipment a valuable one to the repairman. Box No. 4 contains 100 assorted French type gaskets. All assortments are placed in a neat wooden box with steel hinge cover and the different sizes, etc., are located in compartments. Slips accompanying the boxes give the location and sizes. The trade prices will be forwarded upon request, also a catalogue.

NEW SMITH CATALOGUE.

The Joseph N. Smith Company, Detroit, is publishing its 1915 catalogue. The line includes the Ackerman adjustable windshield, screw machine parts and small hardware.

Victor Ford Gaskets.

LEAK-PROOF PISTON RINGS.

The McQuay-Norris Manufacturing Company, St. Louis, Mo., is marketing the Leak-

Leak-Proof Piston Ring.

Proof piston head packing rings, which are a radical departure from the conventional types. As will be noted by an accompanying illustration, the rings are made in two pieces and the construction is on the angle iron principle. Consequently there are no unsealed openings, as the flange of each section completely seals the opening of the other, thus obtaining gas tight construction and making for perfect compression.

The Leak-Proof rings are made concentric, instead of eccentric, and one of the qualities of the design is their equal tension on the cylinder walls.

The Leak-Proof rings are in service in a large number of motors, where trouble has been experienced through oil working up past the original members, and they are held to be decidedly efficient where imperfect compression is experienced. The McQuay-Norris Company is issuing a booklet on piston rings, etc., which contains much valuable and instructive data upon the subject. The brochure will be mailed free upon addressing department D of the company.

BEAN TROUBLE FINDER.

L. H. Bean, Worcester, Mass., is marketing the improved Bean trouble finder shown in the

Bean Trouble Finder.

accompanying illustration. It is designed to locate ignition troubles easily and quickly, and the maker states that faults in coils, short circuits, pitted contact points, loose terminals, magneto troubles, etc., can

be expeditiously determined by its use.

The device is operated as follows: In the event the engine misses, secure the trouble finder to the dash under the hood by the screws provided for this purpose. Attach the ground wire to any metal part of the chassis and start the motor. Take the handle from inside of the box and place the brass end on the terminals near the spark plug. If the spark misses in the glass of the finder, it denotes the coil is not adjusted properly. The action of the magneto may be tested in a similar manner; also all leads, etc.

FRASSE FOLDING TRESTLE.

Peter A. Frasse & Co., Inc., 421 Canal street, New York City, is marketing a patented folding steel horse or trestle, which is designed for garage and repair shop service. It is light, strong and made of high grade material. The legs are

Frasse Folding Steel Trestle or Horse.

provided with a locking device, which makes for rigidity when in service, and the trestle cannot be folded until unlocked. One of the qualities of the design emphasized is that it may be folded and stored in a small space. It is made in standard and special sizes.

DOMESTIC TUNGSTEN LAMPS.

The Domestic Tungsten Lamp Company, Weehawken, N. J., is manufacturing the Domestic tungsten lamp for motor car service. A drawn tungsten wire is utilized and it is stated to have a greater vacuum than any other lamp made for automobile use. The vacuum is first produced by an ordinary oil vacuum pump, then a mercury pump. This is held to insure longer life and freedom from a tendency to become black. The company manufactures lamps in varying sizes and voltages. Catalogue and discounts will be forwarded upon request.

BETHLEHEM SPARK PLUG.

Utilizes Multiple Points, Adapting It to Magneto Currents as Well as Other Systems.

It is well known that the continual sparking between two points of a spark plug when a magneto is utilized as a source of current supply, has a tendency to increase the gap. This decreases the efficiency of the motor and frequently is the cause of difficult starting.

The Silvex Company, 60 Wall street, New York City, claims to have overcome these difficulties in its Bethlehem five-point spark plug, which provides five gaps or paths for the high-tension current. One of the qualities of the design is that should one gap be increased by the burning effect mentioned, the high-tension current would jump one of the other gaps, because of the lesser resistance. Obviously the multiple-point plug provides maximum service and without having to adjust any points.

The Bethlehem is held to be absolutely leak proof, a patented gasket construction being utilized, and it is stated that it is not necessary to prime the cylinders as the points so project into the combustion chamber as to produce a hot spark. Economy of fuel is obtained because of a more complete propagation of the flame. The Bethlehem plugs are constructed to meet the requirements of all internal combustion engines and are made in three sizes, half inch, .875 inch, metric and for motorcycles. The company is issuing a free booklet on ignition, which will be mailed on request.

FINISHES 307-HOUR TEST.

Maxwell 25 Horsepower Motor Expected to Repeat Performance in Public Trials.

Chief Engineer Benner of the Maxwell Motor Company, Detroit, reports that a Maxwell 25 horsepower motor recently underwent a private test covering 307 hours in the factory of the company, during which it performed work equivalent to pulling a loaded Maxwell car, with five passengers, at 25 miles an hour for 7675 miles. It is expected that one of these motors will be subjected to a like test under the auspices of the Automobile Club of America in the near future.

Mr. Benner reports that during the first three days of the test the only adjustment needed was the replacement of two spark plugs. On the third day the gasoline line became clogged and the motor was kept running for several hours

by hand feeding of gasoline to the carburetor. After the feed line had been repaired and replaced, but one other spark plug was changed.

At the conclusion of the test the motor was taken down for examination and Mr. Benner states that although it had been run longer than it would have been in an average year of service, the wear was imperceptible. Tool marks still showed in the cylinders and the greatest actual wear amounted to .0007 of an inch. Connecting rod bearings were in perfect shape, showing no wear, and this condition held true of the push-rods and main bearings. Mr. Benner adds that one of the best indications of the slight wear that took place in the moving parts was in the fact that more horsepower was obtained at the close of the run than at the start.

PROTECTION FOR ITS PLANT.

Marion Motor Car Company Has Not Forgotten the Big Flood of Last Spring.

As the anniversary of the big flood of last spring approaches, Indianapolis has taken extensive precautions to guard against a repetition of similar conditions this year. Chief among the measures to protect West Indianapolis is the construction of a rock bound embankment along White river. This barrier extends well above the high water mark of last year and gives ample protection to that district.

West Indianapolis is the main manufacturing portion of the Hoosier capital. Most of the larger industrial plants are located there. During the floods of a year ago this district was seriously affected, practically all of the families there being forced out of their homes. The plant of the Marion Motor Car Company was thrown open as a temporary refuge, and extensive relief work was carried on under direction of the officials of the company. In addition, the company was seriously handicapped as a result of the flood. The embankment will protect not only the manufactories, but also the shipping facilities, so that it is anticipated there will be little trouble of any sort in the future.

"We are not worrying over the prospects this spring", says F. R. Bump, general sales manager of the Marion company. "Coming as it did at the real start of the shipping season last year, the flood handicapped us to a certain extent, but we are assured a heavy spring business this year and look for no holdup in our manufacturing operations or shipping arrangements. Indianapolis appreciates her manufacturing district and has taken necessary precautions".

NEWS OF THE MANUFACTURER AND DEALER.

The following concerns have been incorporated recently to manufacture or sell motor cars, accessories, etc.:

Stutz Auto Company, Albany, N. Y.; \$10,000; C. E. Graves, M. A. Graves, A. E. Graves.

Thompson-McArthur Inspection Company, New York City; \$10,000; to inspect, test and repair electric motors.

Indestructible Tire Corporation, Manhattan, N. Y.; \$200,000; to manufacture and deal in automobile tires; J. A. Inslee, A. P. Anderson, K. R. Morton.

Indiana Auto Racing Association, Indianapolis, Ind.; \$10,000; Frank Blair, Charles Feeser, Jr., Frank S. Feeser, Benjamin F. Royse.

Rylander Manufacturing Company, Biddeford, Me.; \$400,000; to manufacture motor vehicles; J. A. Snow, F. B. Ross.

Chillingworth Manufacturing Company, Jersey City, N. J.; \$200,000; to conduct a general automobile business; L. Muller, H. W. Bissell, J. F. Moore.

Wagner-Dolph Company, Rochester, N. Y.; \$25,000; to deal in automobiles and motorcycles; G. J. Wagner, W. L. Dolph, E. K. VanAlmkirk.

Kilgore Motor Starters Company, Boston, Mass.; \$15,000; Charles D. McCardry, Frederick O. Kilgore, Augustine J. Daly, Mary E. Daly.

Court Street Garage & Automobile Company, Cincinnati, O.; \$20,000; general garage business; M. A. Bear, E.

Home of the McDuffee Automobile Company, Chicago. Agent for Krit, Peerless, KisselKar and Rauch & Lang.

A. Hauck, J. H. Ahlebrandt, Jr., F. E. Burnett, A. C. Caldwell.

Sneed Automobile Company, Gulfport, Miss.; \$10,000; R. J. Sneed, S. R. Sneed and others.

Guenther-Methundy Sales Company, St. Louis, Mo.; \$10,000.

Mason-Seaman Transportation Company, New York City; \$10,000,000; to conduct a general cab and automobile business; William P. Harding and others.

Jiffy Specialty Company, McKeesport, Penn.; \$25,000; to manufacture automobiles and accessories; George Baehr and others.

Springfield Mend-a-Leak Company, Springfield, O.; \$10,000; to manufacture a filler for automobile tires.

Huma-Swan Company, Chicago, Ill.; \$100,000; to manufacture automobiles; Charles C. George, F. Huma, Willis A. Swan.

S. P. Vaporizer Company, New York City; \$10,000; to manufacture and deal in automobile accessories; J. Von Waddy, S. Y. Beach, R. Stevens.

Automobile Trading Company, New Orleans, La.; \$40,000.

Wentworth Auto Livery Company, Chicago, Ill.; \$20,000; to conduct a garage and delivery business.

Knight Motor Company, Fort Dodge, Ia.; \$10,000.

Blair Manufacturing Company, Boston, Mass.; \$1,000,000; to manufacture automobiles and motors; M. A. Danlher, E. T. Roche, J. B. Lazenby.

American Juvenile Auto Company, Toledo, O.; \$10,000;

to manufacture children's automobiles; C. Murphy, W. C. Bluns, A. C. Lucken, L. M. Smith, J. H. Frick.

A. L. Robertson Motor & Supply Company, New York City; \$22,500; Earlyville Smith and others.

Montauk Automobile Sales Company, Brooklyn, N. Y.; \$5000; Louis F. Ohse and others.

Motokart Company, Tarrytown, N. Y.; \$500,000; to manufacture light delivery wagons.

Skiahook Garage, Skiatook, Okla.; \$4000; to conduct a garage; W. J. Schaefer, C. L. Wall, L. E. Mason.

Vehlen Auto Company, Pierre, S. D.; \$25,000.

Panama Tire & Rubber Company, Albany, N. Y.; \$15,000; A. E. Schwartz, G. L. Lewis, S. V. Morris.

Veldome Company, Buffalo, N. Y.; \$30,000; to promote motor races; William M. Wilson, Dai H. Lewis, F. Vokes.

Waite Auto Livery & Garage Company, Cleveland, O.; \$10,000; to operate a garage; A. F. Waite, J. B. Oviatt, C. E. Hubbell, C. R. Brown, A. E. Rogers.

Auto Repair, Storage & Supply Company, Cleveland, O.; \$5000; to operate a garage; T. A. Cretney, N. H. Reed, C. T. Kirkbridge, F. A. Irvine, J. R. Collister.

Corcoran-Seidel Company, Cleveland, O.; \$25,000; to manufacture and deal in motor car parts; G. S. Case, F. W. Treadway, W. H. Marlatt, F. B. Bolton, R. G. Morrison.

Hillane Garage & Machine Company, Columbus, O.; \$10,000; general garage business; C. Shockey, C. S. Williams, J. C. Langley, F. T. Price, C. M. Carmichael.

Automobile Tire Company of New York, Dallas, Tex.; \$10,000.

Frank Van Syckel Garage Company, \$250,000; to operate a garage; H. W. Picking, C. O. Gyer, F. E. Rugeles.

Long Island Tire Company, Freeport, N. Y.; \$1500; to deal in tires; Marle P. Denton, J. S. Denton, H. E. Weitzig.

Lockport Auto Supply Company, Lockport, N. Y.; \$5000; Arthur L. Hoag, John R. Jelley, Edward H. Huber.

WITH THE MANUFACTURERS.

The S. F. Bowser Company, Fort Wayne, Ind., has created an executive board composed of the officers of the company. A. Z. Polhamus is chairman. S. B. Bechtel has been advanced to become general manager; W. G. Zahrt is assistant general manager and E. H. Briggs has been appointed general sales manager of the central district.

The Hans Motor Equipment Company, La Crosse, Wis., one of the largest producers of pumps and gauges for the motor car manufacturing trade, has taken occupancy of its new works. The Hans company has large contracts with such firms as the Lozier, Cadillac and a number of other prominent companies in the industry.

W. J. Geer has purchased the assets of the Cleveland-Gallon Motor Truck Company, Gallon, O., from the receiver. Mr. Geer represents a number of Gallon citizens, who secured the property with the object of organizing a local company to operate the plant. The company went through a receivership because of lack of capital. It manufactures industrial trucks.

The Emerson Electric Manufacturing Company, St. Louis, Mo., has announced the production of a lighting and charging generator for gasoline automobiles.

The Kelly-Springfield Tire Company, New York City, is to build a three-story addition to its already large and up-to-date factory, to cost \$200,000. The contract has been awarded and work will be started at once.

The W. S. Nott Company, Minneapolis, manufactures a new tire called the Atlas, with tough, cut proof tread, both regular and non-skid.

The Ford Motor Company, Los Angeles, Cal., with the parent house in Detroit, has opened its new assembly plant at Seventh and Santa Fe streets. The plant has a capacity of 100 cars a day and will supply southern California, Arizona and southern Nevada.

The Dayton Rubber Manufacturing Company, Dayton, O., has increased its capital stock from \$150,000 to \$1,000,000, for the purpose of providing additional machinery. E. P. Hooven was elected vice president, E. C. Hooven secretary and treasurer, and John A. McMillan, general manager.

The Mercer Automobile Company, Trenton, N. J., will tender Edwin Pullen, the racing driver, a dinner at one of the Trenton hotels on Saturday evening, April 4, as a mark of appreciation for his sensational Grand Prize victory.

The Hydraulic Truck Company, Los Angeles, Cal., has let contracts for a factory building.

The Monroe Body Company, Pontiac, Mich., manufacturer of automobile bodies, will build an addition to its plant in the near future.

The Universal Tire Company, Los Angeles, Cal., has purchased the building of the Dryfus Winery, Anaheim, Cal., and will remodel the building for the manufacture of automobile tires. H. H. Holloway is president.

The Ideal Steel Wheel Company, Cincinnati, O., is to remove to Elkhart, Ind. The idea of the officials of the company is to get closer to the Detroit automobile market. The new officers of the company recently elected are: President, O. G. Harrison; secretary and treasurer, E. H. Maffey; general manager, T. B. Mills.

The Eberly & Orris Manufacturing Company, Mechanicsburg, Penn., is one of the oldest wheel manufacturing concerns in the United States. The company recently made large and extensive improvements to its plant, and is now in a much better position to take care of its ever increasing business. The plant is fully equipped with the latest machinery, and is one of the most complete automobile wheel factories in the East.

The Willys-Overland Company, Toledo, O., contemplates the erection of a large factory at El Paso, Tex. John N. Willys has just returned from this field and says that a factory in that city would serve California, Mexico, Arizona, New Mexico and Texas.

The New Process Gear Corporation, Syracuse, N. Y., is erecting a new three-story concrete and steel building to provide additional machinery facilities for spur and bevel gear work. This new building is to be absolutely fireproof, with brick curtain walls and concrete floors. The addition will be 40 by 100 feet. The building will be equipped with new machinery throughout.

The Texas Company, New York City, is enjoying much prosperity. The income statement for the six months ending Dec. 31, 1913, is as follows: Gross, \$12,217,198; net, \$3,883,973; sinking fund and depreciation, \$905,763; surplus, \$2,978,210; dividends, \$1,050,000; balance, \$1,928,210; previous surplus, \$7,500,000; total surplus, \$9,428,210.

GARAGE AND DEALER.

The McDuffee Automobile Company, Chicago, which recently took over the sale of the Peerless and Kissel-Kar lines in that territory, has added the Krit, the Krit Motor Car Company, Detroit, following the example of the other concerns in abandoning its Chicago branch. The McDuffee company also handles the Rauch & Lang electric. The officers of the company are: President, H. L. Babcock; vice president, C. S. Englebook; secretary, E. J. Ellis; treasurer, G. A. Pierson. It occupies the four-story building, shown herewith, at Michigan avenue and 25th street, the first floor of which is used for general offices and showrooms, with a garage in the rear. The second floor is used for an auxiliary salesroom and storage, the third for repair work and the fourth as a painting and trimming department.

Charles Rubel & Co., Washington, D. C., has entered the local automobile field with the opening of an automobile specialty house at 1312 14th street. The company will handle accessories.

T. J. Riggs, Bowie, Ariz., will erect a new garage which will be modern throughout.

G. W. Crane and **Clarke Bros.**, Livermore, Cal., have combined and will operate under the name of the Valley Garage Company.

William P. Vanderwolf, Montgomery, N. Y., has sold his interest in the Montgomery Garage & Machine Works to William O. Hall. The new firm will be known as Hall & Knoche.

John A. Matz and **Harry Bannister**, Indianapolis, have formed a partnership and will open a repair shop and cyclecar agency at North Capitol avenue, under the name of the John A. Matz & Co.

F. J. Connor, Turlock, Cal., has purchased a building on South Broadway and will remodel same for use as a first class garage.

Charles F. Dutcher, Naples, N. Y., has bought out the Fisher Bros. garage and will conduct it in the future.

Houson & Treichler, Wilson, N. Y., has purchased land and will erect a large and modern garage, costing \$25,000.

G. W. Jones and **W. J. Brace**, Kansas City, Mo., both well known automobile men in Des Moines, Ia., have formed a partnership under name of Hudson-Brace Motor Company. The company will handle the Hudson cars for this territory. Mr. Jones will continue the Des Moines establishment, and Mr. Brace will take care of the Kansas City section.

R. L. Shumaker, Columbus, O., has opened a repair shop in the rear of 170 North Fourth street. The name of the new shop will be the Auto Repair Company.

Carl H. Pausch, Columbus, O., has established a repair shop and vulcanizing plant at 608 South High street.

E. D. Valentine, Springfield, O., owner of the King garage, now located on West Main street, has purchased the property of John Galer at North Fountain street and will build an up-to-date garage.

Ray Yenter, Iowa City, Ia., has entered the automobile business there, being connected with Wilson & Spencer, Hudson and Studebaker dealer for this territory.

Mat Kille, Guthrie Center, Ia., has leased the building at the corner of De Voe and Commercial streets. He is agent for Auburn cars and will conduct a first class garage.

The Lyons-Atlas Company, Indianapolis, Ind., recently opened its handsome new display rooms at Pennsylvania and New York streets, where Lyons-Knight cars will be presented for the local trade. The accompanying illustration indicates the appearance of the building as

New City Salesroom of the Lyons-Atlas Company in Indianapolis, Ind., Decorated for "Opening Week".

decorated for the recent "Opening Week", which was celebrated by the Indianapolis dealers, in lieu of the annual automobile show.

Lower Bros., Guthrie Center, Ia., has opened its new garage recently completed. The firm has the agency for the Kissel-Kar and Maxwell lines.

Crawford & Hock is the name of a new firm which will open a garage in Blue Hill, Neb.

The Crowley Auto & Supply Company, Fort Worth, Tex., has opened a salesroom in the Denver Record building. Marathon and Metz cars will be shown.

H. C. Wieland, St. Louis, Mo., has opened an electric garage at 4919 Delmar boulevard. The location recently was vacated by the Rauch & Lang St. Louis Company.

Karl R. Rogers and **Harold C. Rogers**, Los Gatos, Cal., have taken over the garage business of W. H. Main, located on West Main street.

C. L. Nickerson, Union, Ia., has purchased an interest in the Yonkers & Roorick garage, Conrad, Ia. He will take charge of the repair department.

Evans & Snyder, Mansfield, Penn., has opened a branch in that city. Headquarters are at Wellsboro, Penn. The company handles the Overland and Studebaker cars.

Fish & Westerberg, Benicia, Cal., has taken over the Benicia garage. It was formerly owned by Charles Clyde.

Val Werner, Memphis, Tenn., has opened salesrooms at 342 Monroe street. Grant cars are handled.

RECENT PATENTS.

Valve for Explosive Engines, John W. Meaker, Detroit, Mich.; No. 1,088,714. Filed May 13, 1912.

Wrench, John E. Monaghan, Fort Morgan, Col.; No. 1,088,716. Filed Aug. 16, 1913.

FAN-TYPE GENERATOR

Bring Your Car Up-to-Date

PUT on a KEMCO and enjoy the Convenience, Cleanliness and Safety of electrical equipment. You can do it at little expense and *without tearing down your car.* The

Kemco

FAN-TYPE GENERATOR

is compact, light and highly efficient. Goes in the one practical place on your car—replaces your fan. No gears, chains or sprockets to eat up power. No complicated wiring.

Cools the motor under all conditions and *fully charges your battery.* Weighs only a few pounds more than the fan it replaces. The KEMCO is making good on hundreds of cars of different makes, from the smallest to the biggest, and from the cheapest to the highest priced. It will make good on yours.

Bosch Magneto

On the Way to Two Million

The demand for Bosch Magnetos is such that within a remarkably few years it has been necessary to greatly increase manufacturing schedules. The Bosch Factories are well on the way to supplying the two millionth magneto.

The Bosch Magneto

remains the one perfectly reliable ignition source and as such it is universally recognized. It is so well made, so carefully designed that its regularity can be depended upon under all conditions. Don't take any magneto or any spark plug.

Service Stations in all important centers of United States and Canada.

H.W. JOHNS-MANVILLE CO.
NEW YORK AND EVERY LARGE CITY

Why should the auto business be different from any other business? To my mind it is not, and the sooner it gets down to a horse sense basis the healthier it will be. The day when it was a "game" is gone. The red fire and hurrah period is past. And the companies which stay in are the ones which are going to adopt a hard-headed, close-margined, business-like policy.

(BUYERS' GUIDE—Continued.)

**"Of the people, by the people,
for the people."**

Lincoln's own words fitly describe the purpose back of the Lincoln Highway. If Lincoln were here and could select his own memorial it would be something useful like this road—something of, and by, and for the people.

Every man cannot be a Lincoln. It is given to all, however, to act in the spirit of Lincoln. The spirit of sacrifice, of devotion to the public good, of pure patriotism.

You would resent the suggestion that you are not patriotic. But what have you done recently to prove it?

Five dollars is a small amount of money. But you can prove yourself a patriot by sending that amount to the Lincoln Highway Association.

There are ten million men in this country who could send this sum and never miss it. And as many more who could send it without hurting. If half this number WOULD send \$5 the success of the Lincoln Highway would be ABSOLUTELY ASSURED.

This Highway will be a magnificent monument to Abraham Lincoln—but as age succeeds age it will be still more a magnificent monument to the common sense, the far-seeing wisdom and the patriotism of the generation—our generation—that built it.

Send \$5 or more today and become a Lincoln Highway builder. Send the Money TODAY while you are in the mood.

If you don't take part in this great work you will have a sneaking feeling of shame all your life whenever the Lincoln Highway is mentioned. Send the \$5 and you will always have a glow of pride in the thought that you helped to adorn your country with this great road stretching like a silver ribbon from blue ocean to blue ocean, binding together states and cities and rural communities in bonds more firm than those of law and language.

Mail \$5 or more today to A. R. Pardington, 2115 Dime Bank building, Detroit.

Pennant illustrated herewith is in four colors at \$1 per pair. (Rights and Lefts.) Decorate your car. Be a BOOSTER.

Space Contributed by The Automobile Journal.

PAWTUCKET R.I.

April 10, 1914

1914

1915

Your car starts in trim for 1914 How will it end?

FRICITION is relentless. It steals mileage that belongs to you. It means lost power, and worn metal. In the end it destroys all motors.

A canvass among New York repair shops showed that about one-half of the automobile engine troubles are caused by incorrect lubrication.

Correct automobile lubrication is an intricate, scientific problem.

Motors and feed systems differ widely. *No one lubricating oil can be efficient for all cars.*

This is absolute.

Your motor has approximately 1500 parts. To reach all friction points properly your oil must suit *your* motor.

Throughout the world, the counsel of the Vacuum Oil Company on lubricating problems relating to every class of machinery is sought by engineers who must meet the most rigid efficiency standards.

In our Lubricating Chart, which will be mailed to any

The various grades of Gargoyle Mobiloils, purified to remove free carbon, are :

Gargoyle Mobiloil "A"
Gargoyle Mobiloil "B"
Gargoyle Mobiloil "E"
Gargoyle Mobiloil "Arctic"

Mobiloils

A grade for each type of motor

VACUUM OIL COMPANY, Rochester, U. S. A.

Specialists in the manufacture of high-grade lubricants for every class of machinery. Obtainable everywhere in the world.

BRANCHES:

DETROIT BOSTON NEW YORK CHICAGO PHILADELPHIA INDIANAPOLIS MINNEAPOLIS PITTSBURGH

motorist on request, represents our professional advice on automobile lubrication. It is a result of the most far-reaching and thorough study of automobile lubrication that has ever been made.

It was prepared after a careful analysis of the motor of each make and model of American and foreign car.

The oils specified have been thoroughly proven by practical demonstration.

For a number of years this Chart, which is annually brought up to date, has been the standard guide to correct automobile lubrication.

Make a note of the grade specified for your car. Then make sure that you get it.

It is safest to buy in original barrels, half-barrels and sealed five and one-gallon cans. See that the red Gargoyle, our mark of manufacture, is on the container.

On request we will also mail a pamphlet on the Lubrication of Automobile Engines. It describes in detail the common engine troubles and gives their causes and remedies.

Gargoyle Mobiloils can be secured from reliable garages, automobile supply houses, hardware stores, and others who supply lubricants.

"All these months of hard usage haven't dulled it a bit."

"The reason for this, Sir, is that I finished it with Valentine's Automobile Painting Materials. They keep a car looking new for many months."

"Note especially the hood and fenders of your car. We put Vanadium Chassis Finishing on them. This varnish is not affected by soapy water washing, mud spotting, road oil and the other evils that attack the finish of the chassis. With other varnishes the hood, fenders and wheels look dull in a few months."

For the body of the car—Vanadium Body Varnish

For the hood, fenders and under parts—Vanadium Chassis Finishing.

Ask your painter to use them.

Write for our booklet, "The Care of the Car". It tells how to keep your car new.

You Pay Too Much For Tires

When You Pay More Than Goodyear Prices

Prices on Goodyear No-Rim-Cut tires have dropped 28 per cent in the past year alone.

Some other tire makers have not met these reductions. But let us see if those high prices mean better tires.

In No-Rim-Cut tires you get these four features found in no other tire in the world:

The 126 braided wires in the tire base—the only way known to make a satisfactory tire that can't rim-cut.

The "On-Air Cure." That is, each tire is final-cured on an air bag shaped like an inner tube. That is done to save the countless blow-outs due to wrinkled fabric. And it adds to our tire cost \$1,500 per day.

The Rivet Fabric breaker strip, for the rights to which we paid \$50,000. It lessens, by 60 per cent, the danger of loose treads.

The All-Weather Tread. A double-thick tread of very tough rubber. As smooth as a plain tread on dry roads, but a sharp anti-skid on wet.

Note that no other tire, whatever the price, offers one of these costly and tire-saving features.

More Mileage

Will higher-cost tires give more mileage? We have had scores of experts working for years to build a tire that gives more mileage. They are in our department of research and experiment. They have made thousands of tests. And they say that No-Rim-Cut tires as made today mark the limit in tire mileage.

And note this: In late years, when most cars carried odometers for measuring tire mileage, No-Rim-Cut tires have outsold any other. In 1913 we sold eleven times as many as in 1909. And all because of mileage records on perhaps 400,000 cars.

The Real Reason

It is easy to build tires to cost less than Goodyears. It is simply impossible to build a tire worth more.

The reason for our prices lies in mammoth output—the largest in the world. It lies in efficiency which results from years of tire-making. It lies in small profits. Our profit last year averaged 6 ½ per cent.

Let these tires show you what they save in trouble, save in upkeep to hundreds of thousands of users.

Goodyear dealers are everywhere.

Polarine

STANDARD

Polarine has proven its worth in town and country, ashore and afloat, for every sort of motor.

Polarine is recommended by the world's largest and most reliable producers of oil, as the best lubricant that science has produced.

Polarine reduces friction to a minimum and ends carbon troubles.

It does not thin out under the greatest cylinder heat, and flows freely down to zero.

Sold in half-barrels and barrels, gallon and five gallon lithographed cans.

Use Socony Motor Gasoline.

J. H. S. SHOCK ABSORBERS

are a revelation as well as a revolution in spring suspension.

Their sensitiveness of action **AUTOMATICALLY** takes up and destroys jars and jolts, either heavy or light, and to the occupant of a car it seems like riding on air—fairly floating through space.

Vibration is eliminated, thus giving long life to tires, motor, transmission and other components. In consequence greater speed is possible, as the car does not tend to skid or roll. The mechanical principle of the J. H. S. Shock Absorber is as scientific as that of a hydro-carbon engine. A cylinder and piston are used to insure durability, there being no fragile parts to wear or easily get out of order. The piston acts in harmony with coiled springs which destroy all shocks.

Twice Around The World

OUR 1914 output of 50,000 cars, if placed but a mile apart, would reach twice around the world.

If placed end to end they would cover a distance of 720,000 feet which would make an unbroken string of Overlands from New York City to Springfield, Mass.

Some cars !

And the point we wish to hammer home is the economy of producing cars in such vast quantities.

Every time our production goes up our price comes down.

That is why we are selling more cars of this type than any other manufacturer in the world.

It is certain that if we did not give more value we could not sell more cars, and the sooner you find this out the quicker you can save yourself considerable money.

The 1914 Overland costs you 30 % less than any other similar car made.

Full information on request. Please address Dept. 52.

Our 10,000-Mile Tests

Reo the Fifth

Is built on a chassis which we have kept running for three years in test cars.

The test cars are kept running at high speed on rough roads. They are run night and day up to 10,000 miles. Then we take them apart and inspect them.

We require that vital parts, after 10,000 miles, shall remain about as good as new.

To insure this, all our steel is made to formula and each lot is analyzed twice. Our gears are tested in a 50-ton crushing machine. Our springs are tested for 100,000 vibrations.

Each driving part must stand a test for at least 50 per cent

over-capacity. After radical tests we take apart each engine and inspect it.

We use 15 roller bearings—190 drop forgings. We use a very costly clutch to avoid clashing gears. And our gear shifting is done by moving a small rod three inches.

Takes Six Weeks

It takes six weeks to build this car as we build it. And it adds one-fourth to the necessary cost of each car.

But the result is a car to keep. Year after year it stays new. And you save trouble, save up-keep, save repairs. Mr. R. E. Olds builds every car as though he built it for himself.

Now \$220 Less

This year's Reo the Fifth sells for \$220 less than last year's model, equipped with electric starter. This saving results from confining our output for years to this single chassis. Now all the special machinery has been charged against previous output.

Yet this season's model with the new streamline body is the handsomest that ever went from our factory. And the best equipped.

You men who buy a car to keep want a car like this. It marks the best that Mr. Olds can do after 27 years of car building. The demand for this car, almost every month, far exceeds our output.

Sold by a thousand dealers. Ask for our catalog and address of nearest show room.

Annual Overhaul and Equipment Number of

THE
AUTOMOBILE
JOURNAL

ISSUE OF APRIL 25

The one subject of interest to owners of pleasure vehicles at this time is the necessary annual overhauling of their machines. This means replacements of parts, equipments, supplies and accessories. It is the buying season with them and requirements prompt their demand.

In this edition advertisers of parts, equipment, accessories and supplies can bring to the attention of 20,000 car owners what they have to offer at a time when they are in the market and when the heaviest buying of the year is done.

The annual overhaul and equipment number of the Journal will deal with this subject in an exhaustive manner and present the kind of practical information that is eagerly sought by every owner and operator of pleasure vehicles.

A partial synopsis of contents is given below. The readers of this edition represent a wonderful purchasing body and this number will be one of the strongest issues ever placed in the hands of car owners.

SYNOPSIS OF CONTENTS

Value of the overhaul and method of ascertaining its extent.
What the owner may accomplish and suggestions for preparation.
How the repair bill may be considerably reduced.
Tools, supplies, etc., necessary in the work and how to select them.
Preparing the cooling system, cleaning and repairing.
Overhauling the power plant and replacing worn components.
Cleaning and adjusting carburetors and fuel tanks.
Attention necessary with lubricating systems.
Cleaning, adjusting and timing magnetos.
Cleaning and adjusting the transmission and replacing worn parts.
Importance of a thorough overhaul of the steering gear.
Relining brakes and inspection of the rear axle.
Steps necessary in placing the storage battery in service.
Electric lighting and starting equipment for heavy and Ford cars.
Accessories and equipment making for comfort and convenience.

Copy accepted to the 22nd.

If your lights
fail suddenly—
What ?
Then ?

Test it out at home, before you try it on the road.

Go into a dark room, with a lighted match. Then blow out the match, and see how long it takes you to see where you're walking. For several moments, you are practically blind.

Suppose you were on a high banked road, or a slippery road, or a dangerous curve, and the same thing occurred.

What might happen before you could see where you were steering?

Electric light depends upon the perfect working of delicate, complicated apparatus. It may snap out at any instant, without a second's warning.

You can rely on

Prest-O-Lite

You **know** it is dependable. You **know** that it safe-guards the safety of your passengers. You **know** that, should you carelessly allow the gas supply to run low, your lights will die down gradually, giving you ample warning.

In addition Prest-O-Lite gives the best driving light. It lights a broad path ahead of the car and at each side—not a spot half a mile away.

And you can easily light and extinguish Prest-

O-Lite from the dash, giving you every convenience. The Prest-O-Lite, or any other **really good** automatic lighter, does this.

Prest-O-Lite consumes no engine power, needs no expert repairs, and doesn't keep your car tied up in the repair shop.

No matter what self-starter is on your car, your headlights should be gas lights. Reliable light is just as essential as fuel.

Get complete information

By using the coupon, you can get complete information on ALL lighting systems—reports of actual tests—road experiences—a world of information on the vital question of lighting. Use the coupon—today.

AND DOES NOT SOOT.

Carbon in your cylinders means loss of power. Customers report 10,000 to 15,000 miles with no carbon trouble. A good motto: TRY ANYTHING ONCE. EAGLEINE NO-CARBON AUTO OIL is furnished in 1.5-10 gallon, 30 and 50 gallon Steel Drums with faucets for which no extra charge is made.

EAGLE OIL
AND SUPPLY CO.

104 BROAD STREET, BOSTON, MASS.

NOTICE

Pursuant to an order duly made by the Referee in Bankruptcy, in the case of Knox Automobile Company, bankrupt, the undersigned will sell at public auction on the steps of the Hampden County Court House in Springfield, Hampden County, Massachusetts, on Friday, the 24th day of April, 1914, at 10 o'clock in the forenoon the following property of said bankrupt.

1. The manufacturing plant of the company, being a parcel of land in Springfield about 120 feet by about 800 feet, bounded on Wilbraham road, Waltham avenue and the railroad, owned or operated by the New York, New Haven and Hartford Railroad Company, having spur track facilities and being in a location easy of access to the centre of the city and also to a good residential district. The buildings of the plant are of regular mill construction.

2. Four other certain parcels of land located near the manufacturing plant and being residential property.

3. All the machinery, materials, raw, wrought and in process and all of the finished product belonging to the said bankrupt estate and all other property and the said estate of every kind and nature, including patents and copyrights, **excepting, however, and excluding cash, bills and accounts receivable, and choses in action.**

Detailed schedules of the above property may be seen at the office of the trustee at the plant.

At the time and place of said sale the trustee will offer said property in lots or parcels in any substantial amount thereof as any bidder may desire. But the trustee reserves the right after having received bids on any lot to again offer the same property as part of a larger lot or to offer the whole of the aforesaid property as one lot if in his judgment it is for the best interest of the bankrupt estate to do so.

The trustee reserves the right to withdraw the whole or any part of said property from sale at any time before the auctioneer announces its completion by the fall of the hammer or otherwise.

The directors of the Knox Automobile Company have passed a vote directing the clerk thereof to deliver to Charles G. Gardner, trustee as aforesaid, a consent in writing that any person or corporation, now existing or yet to be organized, that may buy from him as trustee as aforesaid the manufacturing plant of the bankrupt company, or any person or corporation to whom or to which the purchaser thereof from him may convey such plant, may assume the name of the Knox Automobile Company or any other name similar thereto.

TERMS OF PAYMENT.

Ten per cent. of any bid made shall be deposited with the trustee at the time the bid is made (which shall be forfeited if such bidder shall fail to take and pay for property struck down to him, but shall be returned to him if the property shall not be struck down to him); the payment of the balance of the purchase price may be deferred for such time as the trustee may agree or consent to provided the settlement of the estate is not delayed thereby and provided that all deferred payments are secured to the satisfaction of the trustee; purchasers shall be entitled to use, turn in and apply in making payment of the purchase money, except the 10 per cent. thereof which shall be paid in cash, any proved and allowed claims against this estate which may be owned by them, reckoning the same for such purpose at such sum as the trustee may determine to be the minimum amount to which said purchaser as the holder of such claims will be entitled to receive on the distribution of the assets of the estate.

CHARLES G. GARDNER, Trustee

Of the Estate of Knox Automobile Company,
Bankrupt.
Springfield, Mass., April 1, 1914.

KICK THE GASOLOCK

Or give it a twist of the wrist and your motor car is absolutely thief-proof.

The Gasolock is the safest device yet invented to prevent joy riding and auto stealing. It shuts off the gasoline in a positive manner which only your Yale key can open again.

The Gasolock prevents waste from leaky carburetors with its attendant dangers of fire and explosion; it saves automobile insurance against theft; it saves your car from joy riders and the ruin they leave in their wake. Your peace of mind when leaving your car at the curb is a big item; your convenience in always having your car is another. Over 2000 motor cars were stolen last year. But the Gasolock protected machine is thief-proof.

Over 1000 in Use in Detroit

The Gasolock is highly finished in nickel plate and can be quickly installed on your motor car, motor truck or motor boat. Two Yale keys are furnished with each device, while we keep a third key filed away under your number. If you should lose one or both of these keys a wire sent us collect will bring the third key under special delivery without charge. It is part of our service to our customers.

The Gasolock is guaranteed for life and can be taken from your old car and installed in your new one at any garage. It practically lasts forever.

YOU NEED THIS PROTECTION ON YOUR AUTOMOBILE—It will mean a tranquil mind and a safe motor car. Why not have both by writing us today? Sent prepaid for \$10.00. Can be installed in one hour at any garage.

FORD CAR TURNING HEADLIGHTS

Know what is around the curve in the inky darkness of the country night-time—don't drive blindly and trust to luck. Your family, yourself and your car should be protected.

The Turning Headlight outfits which you can install in half an hour costs you \$10.00 prepaid—a very small sum for such protection. It won't rattle or give you a second thought and is sold with a rigid "Money Back" guarantee if you are not thoroughly satisfied after thirty days trial. Why not write us today—enclose your check or money order—and try out this real necessity on your Ford Car?

PUBLISHER'S AND READER'S PAGE

The Annual Overhaul and Equipment Number of The Automobile Journal will be issued April 25. The articles dealing with the preparation of the car will be comprehensively dealt with and the discussions will be wholly practical. All components of the car requiring attention will be described and illustrated and common sense methods of completing the work outlined. One of the features of the Annual Overhaul and Equipment Number will be the timely suggestions for inspecting the power plant, clutch, transmission, rear axle, etc. Each will be treated separately, enabling the new owner or operator to ascertain readily the repairs and replacements required to obtain maximum efficiency. For the benefit of the new motorist there will be presented an instructive article on the selection of the tools and supplies needed, and valuable advice will be given as to repairs requiring the service of the expert.

Equipping the Garage is a subject in which every motorist is interested, especially the purchaser of a new machine. There is a grow-

ing tendency for the automobilist to maintain his own car and he is always interested in equipment which economizes in time, labor and money. The April 25 issue of The Automobile Journal will contain a special article

on this subject and suggestions will be made for selecting the equipment. The latest devices of this kind will be described and illustrated.

*Indicates article is illustrated.

Particular Attention is drawn to the department describing and illustrating new accessories in this issue. Many practical and useful devices will be noted, and in writing manufacturers always mention The Automobile Journal. The April 25 issue will be replete with new accessories, fittings, etc., and a large number of new Ford specialties will be presented for the first time in any publication.

Always Consult the Buyers' Guide, on pages 87-96, inclusive, when in

need of anything new in cars, accessories, supplies and equipment. The concerns listed are wholly reliable. When corresponding with advertisers mention of the The Automobile Journal will insure prompt attention.

The Name and The Guarantee

When we stamp MULTIBESTOS in bright bold letters on our brake lining we do more than provide for you a means of identifying MULTIBESTOS from other linings not so good.

We say to you: Here is a brake lining we are proud of; a brake lining we are glad to have you compare with any other under any condition of service; a brake lining which we as manufacturers stand back of with a most liberal guarantee.

This guarantee on which we have always sold MULTIBESTOS is liberal and without qualification or condition:

**"That every user of MULTIBESTOS shall be
satisfied without regard to cost or loss to us."**

This is a real service guarantee—a guarantee of satisfaction to the large and growing army of MULTIBESTOS users.

RAYFIELD

CARBURETOR

WIN AGAIN

"Edwin Pullen in a Mercer wins the fifth international Grand Prix Race at Santa Monica, travelling seventy-seven and two-tenths miles per hour for four hundred and three miles."

Brief as it is, that sensational bulletin adds one more victory to the long list of Rayfield conquests.

Two successive victories in this strenuous race—Caleb Bragg in 1912 at Milwaukee and Edwin Pullen at Santa Monica.

Pullen used a Rayfield because he wanted Rayfield results; he expected to break all records for the Grand Prix; he raised the Grand Prix speed three miles per hour and out-distanced his nearest competitor by 40 miles at the finish.

For 35 laps Pullen broke the world's record for speed, travelling 79.2 miles per hour.

Need we emphasize this remarkable showing of the Rayfield Carburetor? Need we tell you who already know the merits of the Rayfield? It is sufficient to say, Look to the records of achievement in the past; base your judgment on the proofs of men who use Rayfield Carburetors because they want the advantages of Rayfield superiority.

Vanderbilt and Grand Prix

Read this List of Rayfield Victories:

Edwin Pullen.....	1914.....	Grand Prix at Santa Monica
Caleb Bragg.....	1912.....	Grand Prix at Milwaukee
Ralph De Palma.....	1912.....	Vanderbilt at Milwaukee
Ralph Mulford.....	1911.....	Vanderbilt at Savannah

The Rayfield is the only American carburetor that ever won the Grand Prix.

BEAUTIES OF THE LAKE TAHOE COUNTRY.

How the State of California Has Helped to Make This Section More Easily Accessible to Motorists and Others---Eastern Tourists May Reach This District Over Two Branches of the Lincoln Highway.

(By A. P. Underhill.)

IN THE near future, the transcontinental motorist will leave New York City, or connect with the route at some other point, and travel westward to the Pacific Coast over the Lincoln highway. He will find many points of interest, but for beautiful mountain scenery nothing on the whole trip will equal the vicinity of the Nevada-California boundary. This is the Lake Tahoe country, located on the eastern slope of the Sierra Nevada mountains.

To those who have never seen this wonderful mountain lake, one can only

say: "Go West and see it". It is utterly impossible to describe its beauties and its charm. Photographs fail to reveal its rich coloring, or that of the surrounding mountains.

In the Heart of the Lake Tahoe Country in California, Where the Rugged Sierra Nevadas Raise Their Peaks Thousands of Feet Above Sea Level.

In general shape, the lake is oval, 23 miles long and 13 wide, with an elevation of 6240 feet above sea level; its surface dotted here and there by small islands, and surrounded on all sides by snow-clad mountains, some of the peaks of which reach an altitude of over 11,000 feet. The waters of the lake, coming from the melting snows of these lofty

Passing Cave Rock on the New State Road Skirting Lake Tahoe Near the Nevada Boundary.

peaks, is pure and clear, while the colors shade all the way from pale greens to the deepest blues.

The motorist who approaches this country from the East follows the Lincoln highway to Reno, Nev., where the route divides, one portion running to the north of Lake Tahoe and following the old Emigrant Gap road, and the other leading to Carson, the capital of the state, thence over the Placerville road around the southern end of Lake Tahoe. Both routes come together

again at Sacramento, the capital of California. It is possible to reach Lake Tahoe by either.

On the Emigrant Gap route, the road skirts the Truckee river to the lumber town of Verdi, at which place it leaves the river and climbs over the "Dog Valley Grade", a steady rise for nearly 10 miles. The motorist will usually take this climb on second speed, for, while it is a long pull, the grade is not over 10 or 12 per cent. in the worst places.

After passing the summit, it is a several-mile coast to Truckee, one of the few remaining western frontier towns of the old type. Still, in keeping with the times, it has moving picture shows, dance halls, plenty of saloons and one of the finest collections of butterflies in the country. The lumberman and Basque shepherd come in here for supplies, and, as there is stock raising in the surrounding country, it is seldom that a cow puncher cannot be seen.

The Truckee river is met again at this point, and the highway follows along the winding canon, the steep, heavily wooded sides of which give a constant change of scene. In some places the canon narrows so that there is just room for the river, the highway and the narrow gauge railroad—and it requires some crowding to get them all in, at that.

After this drive of 15 miles from Truckee, the outlet of the river from Lake Tahoe is reached. Nearby is Tahoe tavern, a beautiful mountain hotel of some 300 rooms, and one of the most popular summer mountain resorts in California. There is an excellent garage connected with the tavern, where gasoline and all kinds of

Emigrant Gap Route, About 15 Miles West of Truckee, Cal., 7000 Feet Above Sea Level, with Donner Lake in the Distance.

supplies for the automobile may be obtained.

If the motorist is at all fond of trout fishing, it would be well for him to secure a rod and some flies before reaching the Truckee river, as that river and the streams flowing into the lake are full of fish. A real trout fisherman would never consider it a hardship to stop driving for an hour or two and try for a trout in some likely looking stretch of the river.

Leaving Tahoe tavern, the road follows the lake shore, passing a number of beautiful summer homes, and running in many places through fine primeval forests of cedar, fir and sugar pine. Many of these trees are upwards of 300 years old, and while they cannot be made to compare with the famous big trees of California, they are six and eight feet in diameter and over 200 feet high. The road is winding, with few grades, and is a good mountain highway.

At McKinney's, eight miles south of Tahoe tavern, the motorist comes onto a state road, which was completed last fall, and which forms the connecting link between the north and south ends of the lake. The California state engineer's department is certainly to be commended for undertaking this stretch of road, for it is without doubt the most beautiful mountain highway in this country.

It is built mainly of rotten granite, which packs down to a hard surface, little affected by the snows of winter. The material has the added advantage of being easily acquired, since most of it is to be obtained on the spot, and none of it needs to be carted any considerable distance.

Snow-Clad Mountain Peaks Across Lake Tahoe from the Lake Shore Road Near Glenbrook, Nev.

Rotten granite has been used in a number of road making enterprises in the mountain districts of the Far West during the past two years. Long sections of the Pike's Peak transcontinental route in Colorado were constructed of this material, blasted out of the mountain side practically on the job. Sections of what will be a continuation of this route in Utah also were constructed in the same manner. The material is

Another View of the Emigrant Gap Route Winding Its Way into the Sierra Nevada Mountains Toward the Lake Tahoe District.

Overlooking Emerald Bay from the State Road Cut on a Granite Shelf in the Mountain Side.

particularly well adapted to motor vehicle traffic.

On this Lake Tahoe road, the grades are easy, nowhere steeper than 10 per cent., so that a small car has no difficulty in making the trip. Along this part of the lake the mountain slopes extend down to the water the greater portion of the way, necessitating the cutting out of a shelf on which the road may pass.

For about five miles the road winds along the slope at an elevation of about 200 feet above the lake, allowing one to have views from all points of the compass. After crossing a fine meadow the motorist begins an easy three-mile climb, winding up through a canon that is behind Rubicon point and the low ridge which skirts the lake shore. This is the only part of the highway on which the lake is not in sight, but shortly after reaching the summit, Emerald bay comes into view.

This bay is an arm of Lake Tahoe, almost completely landlocked, and receives its name from the beautiful emerald coloring of the water. This section of the highway has been the bugbear of the road builder, for the mountains slope so steeply to the water that earlier surveys seemed to show that either the cost would be prohibitive or that the grades would be too severe. In 1911, another survey was made, and, after discarding several routes, one was laid out that could be built within an appropriation which the

state felt it could make, and one that kept the grades down to under 10 per cent.

This was finished last year, and the result is that for about four miles, one drives on a winding shelf on the side of the mountain, blasted for a greater portion of the way, out of solid granite. The view may be imagined, when it is considered that the road is over 500 feet above the surface of the bay. A stone parapet on the outside of the roadway gives a feeling of security, and this, together with the ample width, makes it a perfectly safe road to travel.

One of the views shown herewith indicates in some measure the difficulty which was experienced in completing this piece of work, although the photograph reproduced was taken while the construction was under way. As stated, there is now a stone parapet on the side toward the bay, and the road itself is much wider than appears in the picture.

After making nearly a half-circle, the road comes out onto a "hogback", with Emerald bay on one side and Cascade lake on the other. This point is sufficiently high to give opportunity for an excellent idea of the wonderful beauty and ruggedness of the country. The photograph reproduced on the opening page of this article gives a partial idea of the grandeur of the view, although it is impossible for the camera to depict the entire scene, with its combination of lake

The Steamer Tahoe Rounding One of the Islands in the Beautiful Emerald Bay, Lake Tahoe.

Where the Trout Fisherman May Leave His Car to Try His Luck in the Truckee River, Near Tahoe Tavern.

and mountain unlike that of any other section of the country.

For the next few miles the road runs through forests and across meadows, crossing two or three private estates, and comes out again to the lake shore at Tallac. Tallac is a pleasant summer resort built a number of years ago by "Lucky" Baldwin, and is still owned by his heirs. Those who desire may take an interesting side trip of about 15 miles to Fallen Leaf lake and Glen Alpine, both of which are right in the heart of the mountains.

From Tallac around the southern end of Lake Tahoe, the better road will be found by way of Myers, at that point bearing to the left through Lakeside, passing Cave Rock into Glenbrook, Nev. Here is found a broad, level, grass covered country, extending perhaps half a mile back to the mountains, and with a fine sandy beach along the lake front. The hotel faces the beach and is surrounded by a number of most attractive cottages, all of which are so situated as to command a view across the lake to the snow-covered Sierras in California.

If one wishes to visit the old scenes of "Bonanza" days, when silver mining was the big craze in Nevada, it is a pleasant trip over the "King's Canon Grade" to Carson and Virginia City. This is the route of the old stage lines, and as travel was very heavy then, the road was so well built that when the automobile came it required but

very little expense to make an excellent highway.

In those days, there were 10 six-horse stages each way every day, besides numerous heavy freight teams, and the dust was so bad that the road was sprinkled for the whole distance between Sacramento and Virginia City. From Glenbrook, it is an easy climb of 800 feet to the summit, and during the drop of 2500 feet into Carson, wonderful views of Carson valley may be obtained. This valley is well known throughout Nevada as an excellent country for stock raising.

In describing this route from Lake Tahoe to Carson, the southern branch of the Lincoln highway has been followed in the reverse di-

rection. Continuing west from Lake Tahoe, the motorist has the choice of the two routes—the Emigrant Gap road or the Placerville road—either of which is good and they are about equal in length, Sacramento being about 135 miles distant.

Both are interesting. The Emigrant Gap road passes through the towns of Gold Run and Dutch Flat, made famous by Bret Harte's writings, and the centre of the hydraulic mining region in the early '50's. Colfax and Auburn, also on this route, are thriving places in a fine fruit growing country. It is an easy day's drive of about 100 miles for the motorist from Sacramento to San Francisco and the Golden Gate.

View of Lake Tahoe and the Snow Capped Mountains Beyond from Rubicon Point.

INDIANAPOLIS ENTRIES.

Total of 18 Received, Including Oldfield, Who Will Drive a Stutz, and Ralph De Palma.

Barney Oldfield has been selected as the third driver of the Stutz entries in the Indianapolis speedway race by Harry Stutz, who was very much impressed with Oldfield's work recently. This will give the Stutz a very strong team, Cooper, Anderson and Oldfield.

The entry of the three Mercers and the third Stutz brings the total up to 18, the entry of Ralph De Palma in a Mercedes having been officially acknowledged by the speedway management. The field at present is as follows: Burman, driving his own car; Anderson, Cooper and Oldfield, Stutz; Goux, Boillot and Duray, Peugeot; Keene, Bullet; Chassagne, Sunbeam; Guyot and Thomas, Delage; Christiaens, Excelsior; Klein, King; De Palma, Mercedes; Pullen, Wishart and Bragg, Mercer. Ralph Mulford's Peugeot entry has been declined, it is stated, because of the rule forbidding more than three cars of one make starting in a race run under the sanction of the American Automobile Association.

PASSES LIGHT BILL.

Rhode Island Enacts a Law Compelling All Vehicles to Carry Lights at Night.

Rhode Island has joined the list of states indorsing legislation compelling all vehicles to carry lights at night. The Wilcox bill passed both houses and provides for every vehicle to display a light with the exception of those transporting hay. There was considerable opposition manifested by certain teaming companies at the hearing, but the motorists were well represented by able speakers. The automobilists have been working for some time to have a light bill passed and the result is decidedly satisfactory.

CHANGES IN HUPP COMPANY.

President Drake Makes Announcement of Adjustment of Duties of Officers.

J. Walter Drake, president of the Hupp Motor Car Company, Detroit, has made public recent adjustments of the duties of the officers of this concern. F. A. Harris, who was assistant general manager, has been made commercial

manager with greatly increased duties, while C. D. Hastings, who up to this time has had the title of secretary and general manager, relinquishes the latter's duties. He is still secretary of the company, beside acting in an advisory capacity. Mr. Drake continues active supervision over the general affairs of the concern. Otto von Bachellet, who for the last year has been concerned with the production of a small six, has withdrawn, following the decision not to enter the six-cylinder field.

MOTOR CARS IN NEW MEXICO.

Figures Show a Total of 1699, or About One to Every 200 Inhabitants.

New Mexico has but 1699 automobiles, or one car to every 200 inhabitants, according to figures given out by Secretary of State Lucero. The machines represent 110 makes scattered over 183 cities and towns. Chaves county leads with 361, which is about six times as many as Sante Fe county, which has about the same population.

LARGE MOTOR ORDER.

George W. Jagers Manufacturing Company to Build 10,000 Engines for Argo Concern.

The George W. Jagers Manufacturing Company, Racine, Wis., will manufacture motors for the Argo Motor Company of New York, of which Benjamin Briscoe is the head. The contract is said to be for a term of years and calls for the delivery of 10,000 motors and transmissions by July 31, 1915. The following year 20,000 are to be manufactured.

HOUSEL COMPANY BANKRUPT.

Maker of Ford Motor Starter Lists Liabilities at \$26,163.26—Assets Scheduled at \$10,630.69.

A petition in bankruptcy has been filed by the Housel Manufacturing Company, East Rochester, N. Y., in the United States district court at Buffalo, N. Y. The liabilities are listed at \$26,163.26, while the assets are scheduled at \$10,630.69. Of the liabilities \$19,445.94 are in unsecured claims. Of the assets \$2276 are for outstanding accounts. The value of the stock on hand is \$3531.50. The machinery is scheduled at \$2400. The company manufactured a motor starter for Ford automobiles.

BALANCING INTERNAL COMBUSTION ENGINES.

F. W. Lanchester Discusses Defects of Balance, Torque Vibrations and Possible Arrangements of Cylinders and Cranks---Advantages of Multi-Cylinder Engines.

IN A PAPER read by F. W. Lanchester, a member of the Institution of Automobile Engineers, before that body recently in England, the subject of engine vibration and the balancing of reciprocating parts was discussed. The purpose of the paper was the study of the elementary causes of vibration, and the demonstration of methods by which the elimination of vibration may be effected. The examples taken for the purpose of illustration were such as substantially to cover the ground that ordinarily comes within the purview of the builder of engines of the automobile type.

At the outset it may be stated that there are two fundamentally distinct problems connected with the subject of vibration and balancing between which a sharp line of definition exists. There are vibrations proper to any given engine in which the component parts are assumed as rigid within themselves; that is to say, vibrations which are quite independent of any distortion or spring of the material of which the engine is composed.

On the other hand, there are vibrations, or sources of vibration, which are due entirely to the elastic yielding or springing of the engine components, principally the springing of the crankshaft and engine frame, and vibrations of this type may exist in any engine which, considered as rigid, should be vibration free. In the discussion following, it is assumed that the engine components are in themselves rigid, and the question of engine vibration is dealt with on this assumption. Vibrations due to elastic yielding will be dealt with in an article succeeding the following.

Line of Treatment.

If the problem with which we are faced were not confined and limited by the actual conditions of engine construction, that is to say, if we had required to consider the vibration of an entirely undefined engine or piece of mechanism in its broadest possible aspect, we should take our stand initially on the usual mathematician's or physicist's basis of six degrees of freedom, the meaning of this being that the vibrations may be constituted of motions of translation in any or all of the three co-ordinate dimensions of space or of rotations about any or all of the three co-ordinated axes. Fortunately, however, the problem has not to be treated in its broadest form; the conditions are considerably narrowed by the actual nature and character of the machines with which we are concerned, and consequently we can abandon the generalized basis with advantage, and adopt a specialized treatment as more appropriate to the conditions of the problem.

Narrowed Basis of Treatment.

When we have before us the design of a reciprocating motive power engine, or, more broadly, any fluid pressure engine employing the usual piston and connecting rod or equivalent, we find that the complete symmetry of the problem is disturbed, firstly, by the existence of a definite axis of rotation, that is, the functional axis of the engine—the axis direction of the crankshaft, and, secondly, by the existence of one or more axes of piston motion. When we require to consider the balancing problem, and study questions of forces and moments, we find that the constructional features of the engine aforesaid give us a circumscribed problem in which we know just where to look for our unbalanced forces—the reciprocating parts are confined, to directions at right angles to the crank axes—and in which we look for moments in the form of torque variations when we deal with the crankshaft axes, and of rocking moments when we deal with any axes at right angles thereto.

Two Lines of Thought.

There are two different ways of thinking of any problem in balancing or vibration, which, though not fundamentally distinct, are at least sufficiently different to merit a few words of discussion. We may, for instance, in the case of an ordinary reciprocating engine, consider the bed of the engine as fixed (as if, for ex-

Fig. 1.

ample, bolted to a foundation of overwhelming size), and consider the forces and moments that will result from the functional movements of its parts, or, alternately, we may consider the engine as suspended perfectly freely in space, and study the resultant movements of the engine bed, or of that portion of the engine which is in practice employed as its mounting.

In this latter method of considering the problem, it is necessary to assume a torque applied to the engine equal to its mean torque in the performance of work, in order to prevent its rotating bodily in space. Both the foregoing lines of thought are of value, and are employed in the present paper in dealing with the different phases of the problem.

The Single-Cylinder Engine.

As an initial study, it is convenient to take the case of a single-cylinder reciprocating engine, and to introduce the various defects of balance to which such an engine is subject, one by one. Let us take the elements of a single-cylinder engine and imagine, in the first instance, that the connecting rod is infinitely long, and let us further assume that there is no flywheel, and that the engine is "belted" round without compression. These conditions are naturally impossible of fulfillment, but before we reach the point of discussing the engine as a practical machine, we shall have made the necessary additions to the study as above presented.

Let us suppose that the piston has a mass m , and the remainder of the engine has a mass M . Let us firstly assume that the mass M is fixed, then we have the mass m moving with a strictly harmonic motion through a distance s , by which we will denote the stroke; then at any known number of revolutions R we can calculate precisely the forces that will be set up, acting on the foundation bolts by which the mass M is held, and we know that the motion in question is harmonic and gives rise to forces represented by a straight line diagram as in Fig. 1, in which the maximum value of the force F (in pounds) is given by the expression

$$F = 2\pi^2 m s R^2 / 32.2.$$

If, alternatively, in the above example we suppose the engine frame, that is the mass M , to be free in space, the resultant motion may be derived from the principle that the centre of gravity of a self-contained system cannot undergo change of motion without a force applied from without (this being a paraphrase of the third law of motion); thus, if the centre of gravity of the combined mass $M+m$ undergoes no motion, then it is self-evident that the movement of M will be (under the conditions supposed) a harmonic motion whose amplitude in relation that of m will be inversely as the respective masses, that is to say, s as before being the stroke, the piston will have a motion to $M s / (M+m)$, and the motion of the engine bed will have an amplitude $m s / (M+m)$.

Application of Fourier's Theorem.

Let us now suppose that the simplified conception of an engine be modified to the extent of giving it a con-

Fig. 2.

necting rod of ordinary proportions. Then, as every engine draughtsman knows, the motion of the piston is no longer a simple harmonic motion, but is an unsymmetrical motion, and the accelerations are greater at the in-centre than at the out-centre, the acceleration curve, and therefore the diagram of force, acting upon the engine foundation (assuming that the engine is fixed) being as represented in Fig. 2, where a dotted line shows the curve (straight line) representing the forces as due to the rod of infinite length previously assumed. Now we know that every periodic curve may be resolved by Fourier's Theorem into a number of simple harmonic components, and it is a fact of no inconsiderable importance in connection with the present subject that the Fourier series may, in the present example, be for all practical purposes represented by two members, namely, the main "fundamental" component represented by the sine curve in Fig. 3 at a , and a secondary motion of twice the frequency, sometimes termed the octave component, also a sine curve, shown in Fig. 3 at b . It will be seen, in referring to Fig. 3, that by superposing the ordinates of the two sine curves a and b , a curve c is obtained optically coincident with the actual piston motion plotted (curve d).*

The full Fourier series of the piston movement is actually an infinite series, but of such rapid convergence that only the two first elements are of practical importance to the engineer, though there are cases in which the third member of the series may have appreciable effect.

*The two curves c and d are, as shown, based on different datum lines; if referred to the same datum they would be undistinguishable.

Torque Vibrations.

It will be noted, in considering the problem as far as it has been developed, that the piston of our one-cylinder engine has two positions per stroke when its kinetic energy is zero, and two positions when its kinetic energy is maximum. This betokens that for a quadrant (roughly speaking) after crossing the in or out centre, the crankshaft is doing work on the piston, and for the succeeding quadrant to the next centre the piston is giving up its energy and doing work on the crankshaft; thus there is an alternation of torque twice per crankshaft revolution, or in Fig. 1 the applied torque (that is to say, the torque required to belt round the engine) will be clockwise in the quadrants a and c , and counter-clockwise in the quadrants b and d . This is not all, however; the torque applied to the crank of the engine and acting on the piston through the connecting rod involves an equal and opposite torque applied to the engine bed or frame from without, and thus the crankshaft torque may be regarded as acting directly on the frame of the engine and undergoing two reversals per revolution. Such an intermittent torque is evidently a potential cause of vibration.

Now let us assume that the engine be furnished with a flywheel. The whole of the foregoing facts remain unaltered provided that we regard the torque applied to the crankshaft as that existing between the crank itself and the flywheel; it may be noted, however, that the belting torque, that is, the torque by which the engine is being artificially driven, no longer need correspond to the internal torque of the engine. For the present it is sufficient to call attention to this point; its bearing on the vibration question will be developed later.

We may assume, as the next step, that the condition of compression be added. As we know, the compression in a single-cylinder may take place at every revolution as in a two-stroke cycle engine, or it may take place every alternate revolution as in a four-stroke cycle engine. On the question of vibration, the effect of compression is felt again in the torque variation; thus during the compression stroke work is expended on the working fluid, and during the expansion stroke the work so expended is restored to the flywheel, so that during the half revolution represented by the compression there is a torque acting on the frame of the engine in the direction of rotation, and during the expansion period there is a torque acting on the frame of the engine in the direction contrary to that of rotation. The torque intermittences due to compression (and explosion) and those due to piston inertia are in practise superposed, and the algebraic sum of the two, which is their resultant, is that which acts on the engine bed. Over certain portions of the stroke and at certain speeds these torques may, to some extent, neutralize one another.

The torques due to compression and those due to piston inertia follow different laws; whereas the former are approximately constant in relation to engine speed, the latter vary as the square of the number of revolutions per minute. The question of the interaction of these two intermittent torques will be considered more fully when the multi-cylinder engine is under discussion.

When we add the question of the explosion pressures, we are, in effect, augmenting to the extent of some four or five times the torque during the expansion stroke, that is, an increase of the torque acting on the crank and flywheel in the direction of rotation and on the frame of the engine in the contrary direction; here we have the recoil or kick so well known in the case of single-cylinder engines as the cause of a most disagreeable vibration. Its effect is felt in multi-cylinder engines, in what is frequently referred to as the "pick up" vibration.

Before we can regard our one-cylinder engine as complete, we must assign weight or mass to the crank itself and the connecting rod. So far as the mass of the crank itself is concerned, it may be completely balanced, as is usual, by rotating counter-weights on the opposite side of the shaft, and so treated it ceases to interest us from the present point of view. The connecting rod is a matter of greater subtlety. As a first approximation, we may, as is customary, consider the mass of the rod as divided between the large and small ends, according to their respective weights, the large end mass being treated as part of the crank itself and balanced by an addendum to the rotating counter-weight on the crankshaft, and the small end mass being treated as in effect part of the piston weight.

If the shank of the connecting rod were of consider-

able mass, it is probable that the above approximate method of treatment would require reconsideration, but, generally speaking, and certainly for the purpose under consideration, the above method of treatment is all that is required.

From the foregoing it will be clear that in a single-cylinder engine, apart from unavoidable torque variations, which are in themselves of a serious character, the question of vibration resolves itself into a question of the mass of the piston and the reciprocating parts. Taking a small vertical motor 85 mm by 88 mm running at 3000 revolutions per minute, the forces due to the main harmonic motion amount to about 800 pounds, and those due to the secondary amount to about 180 pounds, making a total maximum at the in-centre position of 980 pounds. It is customary in single-cylinder engines to endeavor to mitigate the gravity of the position by partially balancing the equivalent reciprocating mass of the piston by rotating weights, but it is quite obvious that such a device is, at the best, a rough-and-ready makeshift. The practise, however, although it does not enable the engineer to eliminate vibration from the cause in question, gives him considerable control over its magnitude and direction; the method is, therefore, of more utility than otherwise might be supposed.

If we take the extreme case when the whole of the reciprocating parts are treated and balanced as if they were rotating parts, that is to say, as if their mass were concentrated on the crank pin, it is of interest to recapitulate the well-known fact that the resultant unbalanced forces may be represented by a reciprocation at right angles to the direction of piston motion of equal magnitude to the original unbalanced forces, at least so far as the fundamental harmonic movement is concerned. Thus, if the structure on which the engine is mounted is better capable of taking vibration or of resisting vibration stresses in one direction than in another, the method in question, even as a means of control, may be of extreme utility.

If, as is frequent, half the reciprocating weight be balanced by a rotating mass on the crankshaft, the well-known result is that the unbalanced residue is the equivalent of a mass equal to the added balance weight rotating at the radius of the crank pin in the direction opposite to the motion of the engine, the maximum disturbing force thus being half its original value. For other proportions of rotary balance weight, the resultant motions are reverse rotations in elliptical orbits or various degrees of eccentricity. In some cases the best degree of balance can be estimated or computed by a study of the conditions of the mounting of the engine or the conditions of usage (in railway work, for example, forces tending to produce a vertical pounding action are objectionable; horizontal forces tending to vary the draw bar pull are also objectionable, but in most cases less so), in other cases, as where it is a question of personal comfort, experiment with a variety of different degrees of "over-balance" is the only safe guide. The term "over-balance" is here used to denote the extent of rotary balance added beyond that necessary to balance the actual rotating parts.

The Two-Cylinder Engine.

We will now pass to a brief study of the additional factors introduced in the case of the two-cylinder engine. There are many arrangements of two-cylinder engines, but, firstly, we will consider the ordinary vertical two-cylinder, that is to say, that in which the cylinders are arranged side by side. In this case it may be noted, first, that the main reciprocating forces may act in the same or in contrary direction according to whether the crank pins are in line or opposed, that is, whether they are together or separated by an angle of 180° . In the former case, so far as reciprocating forces are concerned, the problem resolves itself again into that of the single-cylinder engine, but in the latter case a new factor in the vibration question makes its appearance; the main forces due to the fundamental piston motion (not to its octave) are balanced, but as they act at points separated by the distance between the cylinder axes they give rise to a variable torque or moment about a transverse horizontal axis, and it is customary to term moments of this kind rocking moments, as distinguished from the torque moments about the crank axis itself. It is almost unnecessary to point out that in either case the octave vibrations synchronize, so that, whether the two-cylinder engine has its cranks together or at 180° , the forces that give rise to an octave vibration will be present with full severity.

When we consider the question of torque variation, it is clearly desirable in any multi-cylinder engine to arrange the explosion recoil torques of the different cylinders at equal periods of time; in the two-cylinder engine we have been considering this will be consistent with neutralizing the main inertia force only so long as we are dealing with the two-stroke cycle—that is to say, a two-stroke cycle engine with cranks at 180° will have the impulses occurring at equal intervals of time; when we are concerned with the four-stroke cycle the equal spacing of the impulses can only be obtained by arranging the crank pins in line, and thus the designer has to choose between two conflicting requirements, the equal distribution of impulses and the balancing of the fundamental components of the piston motions. This difficulty was encountered some 25 or 30 years ago in the construction of two-cylinder vertical gas engines; in the early engines of this type built by Messrs. Crossley Bros. the piston motions synchronized, that is to say, the balancing of the inertia forces was sacrificed to obtain equal distribution of the working cycles, but after a very few years this type was superseded by a type of engine in which the cranks were arranged at 180° , the question of inertia balancing being found to be the more important factor of the two. To some extent history repeated itself in the development of the motor car engine, until of recent years the two-cylinder vertical engine has been virtually abandoned.

When we pass to the question of the octave component of the piston motion and the intermittent torque due to piston inertia, we find neither of these can be dealt with satisfactorily on the two-cylinder engine in either form without abandoning both of the other fac-

Fig. 3.

tors. It will be necessary to arrange the cranks at right angles to eliminate these as disturbing forces, and bring them down to the status of disturbing couples. Such a crank distribution is generally considered inadmissible.

There is a form of two-cylinder engine which certainly never had the vogue to which it is entitled—the type in which the cylinders are opposed and the cranks are at 180° . An examination of this type of engine shows—firstly, that the impulses are equally distributed; secondly, that the fundamental piston motions are balanced; thirdly, that the octave piston motions are balanced; fourthly, that the rocking moments due to cylinder axis spacing may be made as small as we please. By a little ingenuity and design the cylinders can be arranged coaxially. The only unbalanced features worthy of consideration are the intermittence of torque due to piston inertia already considered, and the intermittence in torque due to the explosion. Without adopting some specially devised means of balancing or going to a multiplicity of cylinders or some form of rotating engine, it is impossible to obtain a more perfect proposition from the balancing standpoint. The author attributes the fact that this type of engine has not come into prominence almost entirely to popular prejudice. The popular idea has been for many years that an engine cannot be right unless it is vertical. It would show quite as high a degree of popular intelligence if an engine were not deemed "the thing" unless painted blue.

In the foregoing section the question of the rocking moment due to the axial separation of the cylinders with their reciprocating parts was touched upon. At the present juncture it is desirable to call attention to the method by which the rocking moment is eliminated in

the types of multi-cylinder engine commonly employed for automobile purposes, that is, the method of symmetrical distribution. The essential point is that the arrangement of the crank throws should be one of "looking glass" symmetry. If we examine the case of the one-cylinder engine in which no rocking moment exists, or the case of the two-cylinder opposed engine in which no rocking moment exists (i. e., with the two cylinders exactly opposite), or that of the four or six-cylinder engine commonly employed in high-class automobiles, it will be found that there is a plane of symmetry at right angles to the crank axis, that is to say, a plane which may be said to represent a reflector, in which the one-half of the engine is a perfect reflection of the other half; thus, in the case of the one or two-cylinder engine the said plane passes through the cylinder centre line, and in the four and six-cylinder engine the plane is situated half way between the middle pair of cylinders. Speaking broadly, it is not strictly essential that a plane of geometrical symmetry should exist; the symmetry may be of a dynamic kind. It is of interest, however, to point out that in the case of all actual automobile engines in which the rocking moment is eliminated, the distribution of cylinders is, as a fact, on a strictly symmetrical basis. It requires no proof to show that an engine possessing symmetry of the kind under discussion is free from rocking moment, since, whatever couple at any instant one-half of the engine may set up, the couple in the opposite half of the engine, being a reflection of this, must be equal and opposite. As an example of a type of engine at one time to be met with in which the rocking moment had not been eliminated, the three-cylinder engine may be cited.

The Ideal Engine.

Passing from the consideration of rocking moment, that is to say, of couples about axes at right angles to the crank axis to those about the crank axis itself, we have to deal with considerations of an entirely different character. The ideal engine from the present point of view would be one in which, as in an electro motor, the driving torque is constant, but no reciprocating engine can be said to have this quality even approximately; the best approximation is obtained by employing a great multiplicity of cylinders. For many years, and, in fact, until comparatively modern times, the question of torque variation was exclusively dealt with from the point of view of the crankshaft; that is to say, in the steam engine, for example, efforts were continually made by designers to get as constant a torque as possible, but always with the end in view of minimizing speed and torque variations on the crankshaft and drive. It was well understood that the greater the torque variation the heavier the flywheel necessary to ensure constant speed, but little, if any, attention was devoted to the question of the torque recoil. When the gas engine came into prominence, and the flywheel at once became a more essential and functionally more important part, the fact was almost entirely overlooked that, although a sufficiently massive flywheel would give the necessary steadiness of running from the point of view of speed variation, it has no influence whatever as affecting the rotational recoil. The author believes that the question was first dealt with prominently in his own patent specification, 15,045 of 1895, but even since that date the question

has been comparatively little understood, and many claims have been made to dispose of the rotational recoil, or, as it is sometimes termed, the "kick", of the explosion, by means that can have no effect whatever, as, for example, the employment of two opposed pistons in one cylinder.

Recoil Torque.

Let us consider the case of a single-cylinder engine, which we will imagine to be provided with some kind of torsion balance, by which the recoil torque about its crankshaft axis can be measured or recorded. We will examine a period comprising one explosion and expansion, and to fix our ideas we will take it that the (brake) effective mean pressure in the cylinder amounts to 100 pounds per square inch; we will assume, as must be approximately the case, that a quarter of this is expended in overcoming the work done externally by the motor during the expansion stroke, thus leaving 75 pounds per square inch as applying an acceleration torque to the flywheel; this will represent roughly six foot-pounds per cubic inch of cylinder volume energy added to the flywheel; if we know the mass and diameter of the latter, we can calculate exactly what increase of velocity this means, and what additional angular momentum the flywheel has received. Now angular momentum received by the flywheel means torque applied to it, and if we regard the whole engine as a self-contained system, then, since the bed and cylinder are not set in opposite rotation, a torque must have been applied to the bed of the engine sufficient in the time of the stroke to impart the calculated angular momentum to the system, and this torque is, in other words, the torque required to resist the rotational recoil of the explosion. It evidently matters nothing whether the cylinder is fitted with a multiplicity of pistons or whether there is an elaboration of connecting rods or link work between the said pistons and the crankshaft. There is a fundamental principle at stake, and as long as energy is stored in the flywheel at each explosion by a torque applied directly or indirectly from the motor cylinder, the equal and opposite torque must be borne by the attachments of the engine, whether it be a foundation or the chassis of a vehicle. There is only one method of evading this intermittent torque known to the author, and it will be discussed later in the paper.

Effects of Torque.

We know that if any given torque acts for a time t , the angular momentum it will communicate is directly proportional to the time t ; thus, in cases where the bed of the engine is not fully secured, the amplitude of the kick of the engine will be greater as the length of time over which the recoil torque acts is greater. Now the torque is virtually independent of the speed of rotation (within the limits of ordinary usage), hence the amplitude of the kick is, in some measure, inversely as the velocity of rotation. It is well known that the roughness of a single or a multi-cylinder engine is greater at low speeds than at high speeds; in fact, this "roughness" is frequently referred to as the "pick up" vibration, since it is felt more acutely when the speed of the engine is low and the throttle is fully open, as when picking up speed from rest or following on a change from a lower gear.

(To Be Continued.)

FERRIS B. FICK PROMOTED.

Abbott Motor Company Announces Several Changes in Personnel of Officials.

Announcement is made by the Abbott Motor Company, Detroit, to the effect that Ferris B. Fick, secretary and treasurer of the company, has taken over the management of the Pittsburg, Penn., branch and the direct supervision of its distributing agencies in a number of states adjoining. He will also act as personal representative of Edward F. Gerber, president of the Abbott Motor Company, whose interests have be-

come so large and diversified as to require assistance.

In addition to Mr. Fick's new duties he will spend a portion of his time at the Detroit plant and will continue to be active in the management of the concern. D. E. Perry has been selected as purchasing agent to succeed Mr. Fick. He brings to this position a thorough knowledge and special fitness for this work.

The Norma Company of America, maker of Norma ball, roller, thrust and combination bearings, has moved its offices from 20-24 Vesey street, New York City, to 1790 Broadway.

SHIP THIRTY-TWO CARLOADS.**Train Load of Cartercars Leaves Factory for Omaha, Neb., Said to Be Record Shipment.**

On March 28 the Cartercar Company, Pontiac, Mich., shipped to the Cartercar Nebraska Company of Omaha, Neb., a train load of Cartercars, consisting of 32 cars or 102 machines. This is stated to be the largest single shipment made by the company into the West. Three carloads to the same concern preceded this shipment.

TRANSCONTINENTAL ROUTE.**Pikes Peak Ocean to Ocean Highway Association Organized at Meeting in St. Joseph, Mo.**

"The Pikes Peak Ocean to Ocean Highway" is the latest development in the transcontinental route situation. The new highway was launched at a meeting in St. Joseph, Mo., recently by the federation and alliance of state and interstate associations already in existence.

The course is from New York through Philadelphia, Washington, Baltimore, Cumberland, Wheeling, Columbus, Dayton, Indianapolis, Springfield, Hannibal, St. Joseph, Belleville, Colorado Springs, Glenwood Springs, Salt Lake City, Reno, Sacramento and Oakland to San Francisco.

The affiliating organizations are: The Springfield Hannibal Highway Association through Illinois, the Hannibal-St. Joseph Cross State Highway Association through Missouri, the Rock Island Highway Association through Kansas, the Lincoln Highway Association through Colorado, and the Utah division of the Pikes Peak Ocean to Ocean Highway Association.

East of Illinois, a co-operative arrangement has been made with the National Old Trails Association to Washington and New York. West of Salt Lake City the route is not finally determined, but temporarily the line of the Lincoln highway is to be used. It is stated that the entire route from ocean to ocean is passable today, and it is the intention through the various state divisions to push the rapid development of every section.

The officers of the new association are as follows: President, C. F. Adams, Chillicothe, Mo.; first vice president, A. Q. Miller, Belleville, Kan.; second vice president, George McIninch, St. Joseph, Mo.; third vice president, Edwin H. White, Springfield, Ill.; secretary-treasurer, A. W. Henderson, Colorado Springs, Col. These officers

with the following constitute the board of directors: W. H. Conway, Springfield, Ill.; Dr. J. R. McConnell, Baylis, Ill.; R. S. Brownlee, Brookfield, Mo.; J. P. Hinton, Hannibal, Mo.; Dr. C. W. Cole, Norton, Kan.; L. A. Libel, Wathena, Kan.; J. K. Rouze, Burlington, Col.; Judge J. W. Deane, Aspen, Col., and two to be appointed by the State of Utah. National headquarters have been established at Colorado Springs, Col.

A. L. GARFORD IS THE HEAD.**Takes Over Dean Electric Company and Organizes Garford Manufacturing Company.**

A. L. Garford, who is president of the Garford Manufacturing Company, is one of the best known manufacturers in the country, having a national reputation as a business man. He organized the Garford Manufacturing Company after purchasing all the property, assets, patents and good will of the Dean Electric Company of Elyria, O., transferring its assets to the new concern. He invested \$150,000 in cash in the new concern for a working capital, which places the company in a very strong financial position, and the fact that he consented to give his name to the new organization is a sufficient guarantee of its success. It will continue the manufacture of telephones, switchboards and electrical apparatus and will increase the production of automobile accessories, which include electric horns, speedometers, lighting and motor starting systems.

A. L. Garford, President of the Garford Manufacturing Company.

The directors of Gray & Davis, Inc., Boston, maker of electric lighting and motor starting systems, have declared a quarterly dividend of 1.75 per cent. on the preferred stock, payable April 1.

IMPORTANCE OF COACH MAKER'S ART.

Increasing Demand for Enclosed Body Types Has Induced Many American Carriage Builders to Enter This Field--Some Features of Foreign Designs.

ANALYSIS of the models offered by American motor car manufacturers for the 1914 season reveals that a much larger percentage of

Fig. 1—Couch Arm Chair Design, Produced in Germany.

such makers are producing enclosed types than ever before. And it also is of interest to note that there are a number of concerns heretofore engaged in the strictly high grade carriage business who are turning their attention exclusively to this field. It may not be too much to suggest that in the near future, possibly in 1915, provision will have to be made at the annual automobile shows for a special division devoted to body construction, following the practise long established abroad.

In Great Britain and on the Continent, it is the rule, rather than the exception, to sell the chassis and body separately. In fact, it may be said that it is only within the past few years that any foreign chassis manufacturer has catalogued standard body types, and, in a measure, this departure has been due to the necessity for meeting American competition with American methods, insofar as these may prove practicable under European conditions.

The European coach maker has gained a reputation quite as enviable as that of the chassis builder. The names of Kellmer, Van den Plas and some of the others are almost as well known to motorists on this side as those of the car to which their work is fitted. Indeed, many American machines have been supplied with bodies made abroad by these coach makers.

It may be contended that the same situation

will never exist in this country. Yet the motor-ing public may not be aware of the increasing demand for enclosed bodies which has arisen during the past year, and it is along this line that the American coach maker, if such he may be termed, has directed his efforts most largely.

It cannot be said that the American motor car designer has at any time attempted to force public opinion. Innovations have been suggested or offered, but the few makers who have sought to create a demand for something for which the prospective purchaser was not prepared are in a position to realize the value of popular approval. If more enclosed body models are listed this year, it is because the public has demanded them.

As early as last November, Boston dealers were urging the factories they represented to make every effort to supply the demand for this type of body, which had developed in that district. In December, New York City distributors had disposed of their full allotment of enclosed bodies from the factory and were contracting with special body builders in this country and abroad to make up the deficit on orders already received.

Several well known American carriage builders have been engaged in automobile body work for some years. In the first place, these concerns

undertook this work for parties who purchased foreign chassis and desired distinctive bodies. In most instances the transition from carriage to motor car designing has been so gradual as not to excite comment. However, it now appears

Fig. 2—Limousine Interior Revealed at St. Petersburg Show.

that the pioneers in this field were to prove a nucleus of a highly important branch of the automobile industry in the United States.

Fig. 3—Another German Design, Suggesting Drawing Room Interior.

Within the past six months concerns in all sections of the country have been announcing their withdrawal from carriage work, in order that they may be able to devote their entire time and attention to the production of automobile bodies. Included in this list is one of the oldest carriage building firms in America, a concern which was established in 1813 and which has been prominent in its field for a century. Among its most notable productions was the coach utilized by Lafayette upon the occasion of his visit to this country in 1824, which has now been placed in an historical museum. It also specialized in railway coaches, and built the cars used in the first railway train in America, on the pioneer line between Albany and Schenectady, in 1831.

It hardly will be expected that the American coach maker will confine his efforts solely to enclosed bodies, but it is along that line in which the greatest possibilities are offered, as is evidenced by the body work revealed at the foreign shows this season. However much past exhibitions have presented conceptions molded and influenced by orthodox forms associated with the horse, this year's shows in Paris, London, Brussels and St. Petersburg, in particular, were characterized by a large number of original and distinctive creations, embodying ideas calculated to provide for all tastes and requirements, and indicating the importance attached to this type by the foreign designer.

Accompanying illustrations serve to suggest, in some measure, the tendency which may be described as departing from the accepted standards of the coach and approaching those of the

drawing room. It is more or less true that certain Continental designers have been working toward this end for some time, but the progress has not been so marked heretofore.

There is a strong suggestion of the parlor sofa, both in the style and finish of the rear seat of the limousine, presented at Fig. 1. This design is favored by a number of German coach makers, although, of course, the details are not executed in the same manner in each instance. This particular conception is by a Berlin concern, while a Leipsic designer has worked out this same idea in an even more elaborate manner, in that the seat, which in this instance is with straight, plain back with blocks above, is padded throughout and the blocks appear in the seat itself, the back and along the base at the front.

Fig. 2 presents a design seen at the St. Petersburg show. In this case the rear seat is not divided, but the upholstery is strictly in keeping with the other interior fittings. It also will be noted that the single dome light, which, when it was first introduced, was expected to fill every want in this respect, has been replaced by the triplex dome light. This is by no means regarded as sufficient by some designers, who add so-called reading lamps at either end of the rear seat, or four small lamps near the corners on the head linings, etc.

Fig. 3 illustrates another German design, in which it would appear that the drawing room feature had been carried to an extreme. But comparison is invited with the Belgian creation at Fig. 4. There is a certain note of refinement

Fig. 4—Drawing Room Treatment as Presented by a Well Known Belgian Designer.

and coziness about these interiors which is wholly unexpected in the motor car.

In the trimming of the interior of most enclosed bodies there is the same general use of Bedford cord, or some such material, that has made itself apparent in this country more recently. In other cases the cloth or leather matches the color scheme of the painting. In England, particularly, all seats are made with a full amount of pitch, this applying to the couch arm chair design, similar to that illustrated. A few of the bodies, especially those by Continental builders, have silk curtains and blinds, finished with ball fringes, and silk down cushions to rest the back or head against are used in some instances.

Apart from the squabbing and cushions, it has become the general practise to finish the interior of enclosed bodies with polished wood,

Fig. 5—The Interior View of a Modern German Made Omnibus.

used entirely or in conjunction with the cloth. In this respect extremely good taste is displayed in the choice of the many beautiful woods employed. In one car the roof, doors and front may be finished in sycamore, with a device worked out in deep red moldings. Bird's eye maple, ebony, walnut and satin wood, together with fancy colored wood bandings, inlays of marquetry work in scrolls, vases and other devices, are used to ornament the interior, and when the body is lighted with electricity, as is more often the case, a rich, as well as pleasing, effect is the result.

Several bodies are finished in dark Spanish mahogany, with a gold banding inlay, while in others are to be seen the white sycamore, with black ebony inlay, finished with silver and mother of pearl fittings. A very effective finish

to the roof may be made by using the colored woods to form a device, the sections being filled in with cloth of the upholstery, and having the electric light bulbs dropping from each angle. This treatment is more noticeable in the Continental designs, some suggestion of it being presented in Fig. 3.

Much interest attaches to the many contrivances fitted to the interior, not only the cases with watch and stationery compartments, but those containing toilet requisites, which are often of the most costly description. In some bodies there is a miniature roll top desk in polished wood, under lock and key, containing all that is usually to be found in such desks, with drawers for putting away small articles for safe keeping.

The drawing room feature is combined with milady's boudoir in many instances, the front of the interior compartment being fitted with drawers and cases of the finest cabinet finish, and with electric lights so placed near the cabinet work as to afford every homelike appearance. These cabinets also are made for gentlemen's use, and in some cars they are distributed about the entire interior.

It may be added that electricity is being used most extensively in the enclosed cars abroad, whatever the situation with respect to open cars. Electric lights are applied to the flower vases, and push buttons, located within easy reach, make electricity available for all the uses it can be made to serve.

The ventilation of the enclosed body is an important point which the foreign designer has not overlooked. In several instances the front light is utilized in combination with sliding the forward half of the roof backward, so as to obtain a free current of air without creating a draft.

With very few exceptions all the windows utilized on enclosed bodies exhibited by foreign coach makers this year were of the frameless type, several devices being used by different makers to obtain the movement and prevent rattle. Generally speaking, the total height from the ground is much lower than formerly, while the curved roofs are of such height and the doors of such width as to permit of easy ingress. A low step for entry meets the exigencies of the tight skirt, and the door handle is of a pattern that can be moved readily by daintily gloved hands.

When the situation abroad, as revealed by the shows mentioned, is entirely summed up, it may be held that there is less tendency toward the unusual in exterior appearance and greater attention to providing comfort and convenience in the interior.

GENERAL NEWS OF THE INDUSTRY.

Plant of American Motors Company Sold to Chicago Concern--Second Knight Patent Issued--Kline Motor Corporation Buys Plant in Richmond, Va.

THE plant of American Motors Company, Indianapolis, was sold to Samuel Winternitz & Co., Chicago, this concern making the highest bid of \$110,000 at the sale held March 30. The sale, however, is subject to the approval of Judge Albert B. Anderson of the United States court in which the receivership and bankruptcy proceedings are pending.

Samuel Winternitz announced that it is the intention of his company to resell the property piecemeal, which means that the American underslung car will pass out of existence. The sale was conducted by A. Greenwald, auctioneer, for Frank E. Smith, receiver. The plant had been appraised at \$94,000 and the terms of the sale were \$20,000 deposited at the time of the sale and the remainder to be paid in 10 days.

There were about 20 bidders and the contest narrowed down to the successful bidder and Mr. Finnegan of Buffalo, N. Y., who recently bought the E. R. Thomas Company plant. The purchasing concern has bought several motor car plants during the last few months, these including the Michigan Buggy Company, the Falcar plant, the Midland, Grabowsky and others. There was no real estate involved in the American sale. It was thought that some of the old stockholders would attempt to buy in and reorganize the company.

DECLARES DIVIDEND.

Chandler Motor Car Company to Pay Second on Preferred Stock Since July 1.

According to a dispatch from Cleveland, O., the board of directors of the Chandler Motor Car Company has declared a second dividend on the preferred stock of \$200,000. This completes payment of earnings on this stock since beginning of the organization of the company, July 1 last.

KIRKHAM ASSETS SOLD.

Doctor Buys Building and Will Utilize It for a Hospital, It Is Stated.

The assets of the bankrupt Kirkham Motor Company, Bath, N. Y., were sold to Dr. Douglas H. Smith for \$5010. It is stated that the pur-

chaser intends to use the building for a hospital. The machinery and tools were sold to A. R. Morris of Newark, N. J., for \$8050. Other materials brought various sums. Of the total amount realized \$12,910 will be devoted to meet an outstanding bond issue. This will leave approximately \$1075 for partition among the general creditors, whose claims aggregate \$60,000.

BONNELL RESIGNS.

Was Assistant General Manager of National Automobile Chamber of Commerce.

H. A. Bonnell, assistant general manager of the National Automobile Chamber of Commerce, has resigned to accept the secretaryship of the Manufacturers' and Dealers' Motor Underwriters, an organization formed recently by a large number of motor car manufacturers and others prominent in the automobile industry. He takes up his new duties at once.

Mr. Bonnell has been actively identified with the automobile industry for a number of years. He was manager of the Automobile Board of Trade until it was merged into the present National Automobile Chamber of Commerce. He has been treasurer of the American Automobile Association for a number of years.

KNIGHT PATENT ISSUED.

Second to Be Granted Covers Present Engine and Puzzled Examiners for Eight Years.

Charles Y. Knight has been granted the patent on his double-sleeve engine for which he applied June 4, 1906. The patent was granted March 24 and the number is 1,090,991, and is assigned to Knight & Kilbourne Patents Company of Chicago, a corporation of Delaware.

This patent, which puzzled the examiners for eight years before being issued, also includes a system of lubrication especially designed to feed oil to the upper part of the sleeves. It has 43 claims, which cover the sleeve valve action and the lubricating device. These include the two reciprocating sleeves, their method of reciprocation, the ports within the sleeves, and the sealing of the combustion chamber by the junk ring.

This is the second Knight patent to be allowed in this country. The first was granted Aug. 23, 1910, and covered a single reciprocating sleeve design.

UNITED STATES MOTORS CLEARED.

Last Claim Filed Against It by Carlson Motor & Truck Company Settled.

The last claim against the defunct United States Motors Company has been settled in the United States district court at New York. The claim for \$500,000 was filed by the Carlson Motor & Truck Company and resulted from a suit against the Maxwell-Briscoe Motor Company for infringement of the Carlson patent No. 797,555, covering the cover plate used on the old two-cylinder opposed Maxwell motors.

Carlson claimed \$500,000, but it is understood that this sum was not given the complainant by the Maxwell Motor Company, which made the payment. The latter, which still supplies parts for all of the old cars, has been given a license under the patent.

TO MAKE LIGHT CAR.

New Canadian Concern Organized to Build Machine to Be Called the Herman Johnson.

A dispatch from Fort Erie, Ont., states that the Johnson Motor Company is to be incorporated shortly with a capital stock of \$1,000,000, and that it will be a close corporation, with no stock for sale. The plant is to be constructed on the west side of the Grand Trunk Railway tracks. The total cost of the factory is to be \$200,000. It will have three wings and employ about 1500 skilled hands.

It is stated that the machine to be constructed will be made to retail for \$250, will carry two persons and will weigh about 375 pounds. All of the parts will be made at the factory, with the exception of the tires. The new car is to be called the Herman Johnson.

KLINE BUYS PLANT.

Closes Deal Whereby All of Its Product Will Be Manufactured at Richmond, Va.

Announcement was made at Richmond, Va., recently that, owing to a deal closed by the Kline Motor Corporation, the concern will manufacture the whole of its product at the plant in that

city. It was announced that James A. Kline, general manager, had purchased a large amount of rough and finished material at the receiver's sale of the Kirkham Manufacturing Company at Bath, N. Y., and that it would be shipped to Richmond.

The new arrangement is held to mean that the Kline company will double its number of employees. It has a model plant, with a capacity of approximately 1000 cars a year. The buildings are 500 feet in length and are so constructed that there are two wings 60 feet wide with railroad tracks in the centre for the unloading of the material and loading of the finished product.

E. F. GERBER WINS SUIT.

Trustee of Michigan Buggy Company Fails to Substantiate Claims Against Pittsburg Man.

The suit brought by the Detroit Trust Company, trustees in bankruptcy for the Michigan Buggy Company, Kalamazoo, Mich., against E. F. Gerber and his associated companies, engaged in distributing the products of the bankrupt concern, has been settled in favor of Mr. Gerber, who paid \$50,000 for all claims and in return had transferred to him accounts, motor car parts and claims worth \$67,000.

The Detroit Trust Company claimed that Mr. Gerber owed \$404,000, which was denied, and a counter claim made that the Michigan Buggy Company owed Mr. Gerber. In the settlement made his claims were substantiated.

Mr. Gerber and his various companies had for years taken from one-half to two-thirds of the output of the Michigan Buggy Company, selling it in 14 states. Mr. Gerber, in order to conserve his sales organizations, agents and customers, recently purchased the Abbott Motor Company.

WILL PAY DIVIDEND.

Creditors of B. F. Board Truck Company to Receive a Payment of 40 Per Cent.

The 58 creditors of the B. F. Board Motor Truck Company, Inc., of Richmond, Va. will receive about 40 per cent. of their claims according to a statement made by William H. Gaines, clerk of the United States district court of that city. He will distribute \$9463.79 within a few days, and it is stated that a further dividend of from 25 to 30 per cent. will be paid within a few months.

MARYLAND ELECTRIC TRUCK.**Vehicles of Various Carrying Capacities to Be Produced by New Baltimore Concern.**

The Maryland Electric Vehicle & Manufacturing Company has been incorporated in Baltimore, Md., for the purpose of producing the Maryland electric truck. William Knoblock is general manager.

It is understood that the concern will specialize at first upon the production of a 1000-pound wagon, models of which have been in use for some time. Later, it is stated, other models will be added, these having carrying capacities up to five tons.

TIFFANY BECOMES FLANDERS.**Another Change in Name for Pontiac Company Engaged in Developing Electric Car.**

Detroit automobile circles learn that the name of the Tiffany Electric Car Company, which some time ago took over the assets of the Flanders Manufacturing Company, Pontiac, Mich., has been changed to Flanders Electric Company. The old Flanders concern was engaged in the production of electric cars, and its successor, the Tiffany company, has been at work on the development of a new low priced model of the same type.

The newest company, which is said to include E. Leroy Pelletier and Morris Rothschild, the latter of the Harris Bros. Company, has located its headquarters in the Dime Savings Bank building, Detroit. It has not been made public whether or not the name of the car is to remain as the Tiffany, or be changed to Flanders.

ANOTHER TIRE COMPANY.**Concern Incorporates for \$1,500,000 Under the Laws of Connecticut.**

The Norwalk Tire & Rubber Company has been incorporated with capital of \$1,500,000 under the laws of Connecticut, and it is understood that it will locate a tire factory in South Norwalk, Conn. The incorporators are: Earle Banks, John Pierce and Sayer Youngs, all of South Norwalk.

While no public announcement has been made, it is stated that the moving spirit in the new enterprise is W. B. Miller, who formerly was connected with the Diamond Tire & Rub-

ber Company, at Akron, O. It will be noted that his name does not appear in the list of incorporators.

TO MANAGE FIAT SALES.**Well Known Alco Man Takes Charge of That Department for Poughkeepsie Concern.**

Announcement is made in New York City that C. Arthur Benjamin has been appointed manager of sales for the Fiat Automobile Company, with headquarters at the factory in Poughkeepsie, N. Y. It is understood that while his work will embrace the entire country, H. T. Clinton, who has been with the Fiat company for some time, will act under him in the district east of Chicago.

Mr. Benjamin is well known in the industry, and has a wide reputation for his ability as a salesman. For a number of years he was sales manager for the American Locomotive Company, before that concern gave up the manufacture of Alco cars last year. Since that time he has been engaged in closing up the Alco affairs and looking after its service department.

ADOPTS NEW POLICY.**Goodyear Tire & Rubber Company Retires from the Retail Selling Field.**

Another tire concern has retired from the retail selling field, this being the Goodyear Tire & Rubber Company, Akron, O., which made this announcement prior to April 1, at which time the new policy went into effect. Hereafter, no car owner will be able to purchase a casing over the counter in any of the company's 60 branch houses throughout the country.

In arriving at this decision the Goodyear company follows the example which was set in 1911 by the United States Tire Company, soon after the consolidation of the constituent companies which go to make up that concern. The branches will conduct a wholesale business only, leaving the retail field open to competition among dealers.

ANOTHER KNIGHT MOTOR.**Company Formed in Cleveland, O., to Produce Engines for Low Priced Cars.**

According to reports from Cleveland, O., the Knight Engine Company has been organized in

that city for the purpose of producing motors of the Knight sleeve valve type, for use in cars selling for about \$1500. It is understood that the incorporators include Charles Y. Knight, inventor of the motor; L. B. Kilbourne and F. E. Lonas, representing the Knight interests, and a number of Cleveland capitalists.

Such Knight motors as are now on the American market are produced under license by the concerns making the cars in which they are utilized. It is stated that Mr. Knight has been seeking for an opportunity to produce engines for sale to the American trade, and this appears to be an effort along this line.

MOTOR COMPANY CHANGES HANDS.

Pittsburg Model Engine Company Acquires Property of Model Gas Engine Works.

Announcement is made to the effect that the Pittsburg Model Engine Company has purchased the property of the Model Gas Engine Works and that work will begin shortly upon the erection of a new factory at Pittsburg, Penn. The Peru, Ind., plant will hereafter be operated as a branch of the Pittsburg factory.

The management will remain practically the same as that of the old company, and with increased manufacturing facilities the company will be in a better position to serve its customers than heretofore. Until the Pittsburg factory is completed all letters should be addressed to the Peru office.

The officers of the new company are as follows: President, W. J. Strassburger; vice president, E. A. Myers; treasurer, J. F. Keenan; secretary, J. W. Littlefield. It is stated that the new plant will be completed in July.

RECEIVER APPOINTED.

Detroit Trust Company Is Trustee in Bankruptcy for Herreshoff Motor Company.

According to a report published in Detroit, Lee E. Joslin has appointed the Detroit Trust Company trustee in bankruptcy for the Herreshoff Motor Company which, according to its schedule, has total liabilities amounting to \$142,819.84 and assets of \$321,821. An appraisal of the assets has not as yet been made.

Of the total liabilities set down in the schedule, \$85,620.03 is secured and \$52,863 unsecured. The custodian has appraised the machinery, tools and equipment at \$4263 and merchandise at

\$31,358. An appraisement is being made with a view of ascertaining whether the plant should be operated or not.

EMPLOYEES PRIVILEGED.

Production Manager Richman of Cole Motor Car Company Employs a Novel System.

Production Manager J. F. Richman of the Cole Motor Car Company, Indianapolis, Ind., is very popular with the employees because of the method of supervision he utilizes. He explains his success with the workmen by stating that he has always made it a practise to give every man who is a subordinate the privilege and opportunity of expounding his version of the subject that is uppermost in his mind.

"Invariably his troubles to him are important", says Mr. Richman, "and by allowing him to free his mind he goes away feeling that he has been heard and accorded a square deal. This manner of handling employees is generally satisfactory and has a strong influence on the men. The fact that it is their privilege to come to the manager when occasion arises, makes them feel that they are treated as real men; consequently, they continue at their work better satisfied and remain loyal to the company".

ANOTHER FORD PLANT.

Canadian Demand Results in Plans for New Factory at London, Ont.

Owing to the fact that the Walkerville factory is unable to keep up with the demands made upon it by Canadians, the Ford Motor Company of Detroit has decided to establish another branch at London, Ont. A Detroit architect is now working on the plans for a four-story structure which will be modern in every respect. The proposed plant will be utilized as an auxiliary, it is stated, where cars may be assembled and stored and repairs made.

GMC DECLARES DIVIDEND.

Will Pay 3.5 Per Cent. on the Preferred Stock on May 1.

The board of directors of the General Motors Company at a recent meeting in New York City declared the semi-annual dividend of 3.5 per cent. on the preferred stock of the company, payable May 1.

NEW ACCESSORIES FOR THE MOTORIST.

MOSSBERG VALVE GRINDERS.

Made in Two Styles, One Particularly for the Ford Motor.

The Frank Mossberg Company, Attleboro, Mass., is manufacturing two types of valve grinders for the model

T Ford motor. That at the left in the illustration is termed the No. 600 and is designed after the repairman's favorite method of grinding valves, that of utilizing a rolling motion between the flattened hands. The Mossberg tool is so shaped that it fits the hand easily. It is made of hardened steel with wooden handle and is 4.5 inches high.

The Ford valve grinder No. 605 is constructed to permit of swinging a 90-degree circle, has a body of high grade metal and a wooden top. It is designed especially for the Ford owner and is a very practical tool for the person who cares for his own machine. Both grinders are provided with pins which engage with recesses in the valve heads.

SMITH DUPLEX LAMP.

A Combination Dash and Inspection Light with Winding Spool.

Experienced motorists realize it is a dangerous proceeding to utilize a naked flame about the car when inspecting or making an adjustment at night when on the road or in the garage as more or less combustible vapor is present.

An electric lamp makes for safety, and among the late types of inspection members is the design marketed by J. W. Andrews & Co., Chicago. The Smith Duplex, as it is termed, is a combination unit, in that it combines the qualities of a regular dash light and a trouble lamp. The lamp is fitted into a socket in the dash, and, when the use of an inspection light

is required, it may be removed easily and quickly. Sufficient length of high grade flexible cable is provided to permit use of the light at the rear of the machine if desired.

One of the features of the Smith Duplex is the method of carrying the cord. Instead of storing the equipment in the tool box as in conventional practise, the wire is wound upon a spool placed behind the dash. The winding member is neat and compact, as will be noted by the accompanying illustration. The Smith Duplex lamp comes complete with instructions for installing and the work may be performed easily.

CARBONOX.

A Carbon Remover That Is Inexpensive and Practical.

Carbon is present in the cylinders of the internal combustion engine, the amount of the deposit depending upon the grade of lubricant and the quantity utilized. Formerly it was deemed necessary to dismantle the motor to remove it, but in these days it can be displaced easily. The North-

western Chemical Company, Marietta, O., has been marketing for some time a carbon remover called Carbonox, a fluid, which is injected into the cylinders. The preparation does not dissolve the carbon, but attacks the charred oil that fastens the flakes of carbon to each other and to the cylinder, piston head, etc.

The method of use is simple. Carbonox comes in a can having a detachable spout and by means of the latter the fluid is injected through the spark plug opening. The result is that the carbon is loosened and is blown out in the exhaust. The amount present may be noted by holding a sheet of paper under the outlet. One of the qualities of Carbonox is that it provides an inexpensive method of keeping the cylinders free from carbon, as the cost a cylinder is but a few cents.

Attention is specially directed to the April 25 issue of The Automobile Journal, which will be the annual overhaul and equipment number. An effort will be made to present in this department descriptions of equipment making for economy of time and labor. Manufacturers' data must be in the hands of the editor not later than April 18 to insure its use.

CALNAN TIRE REMOVER.

Is Adapted to All Types of Tires and Rims and Ford Shoes.

James P. Calnan, West Upton, Mass., is manufacturing the Calnan tire remover, which is held to be a

very practical tool in that it is designed to loosen any type of tire or rim. One of the qualities of the construction emphasized is that it will fit all sizes.

The tool is operated from the front of the wheel, either when removing or replacing a casing, and it locks automatically, enabling the user to employ both hands if necessary. The equipment also includes a tire removal tool (not shown), which is provided with a ball end that is placed on the ground, and the other end is inserted between the shoe and the rim. By turning the wheel the tool separates the casing from the rim.

RUSCO FORD BRAKE LINING.

Constructed for Service Brake and Is Free from Metal.

While it is a well known fact that the output of the model T Ford fly-wheel generator is very large, the efficiency of the current producer is affected by metal particles, as these short circuit the dynamo. As the service brake band is located in practically the same housing, it is important that it should be lined with a friction material free from any metal.

The Russell Manufacturing Company, Middletown, Conn., is producing a special lining for the Ford brake, which is constructed of long fibre asbestos without wire or other metal. It comes in exact lengths for the brake, in a neat box, and sufficient rivets are provided for securing the material to the drum. The Rusco lining has a very high coefficient of friction and is very durable.

KNOWLSON SPRING SPREADER.

Chas. E. Miller Marketing an Inexpensive Practical Tool.

In these days of refinements more attention is being given to details formerly neglected. Few motorists

consider the springs as requiring attention, but it is a well known fact that these members should be lubricated; that is, the bearing surfaces of the leaves. The old method of cleaning and lubricating consisted of prying the leaves apart with a cold chisel or other convenient tool.

Chas. E. Miller, 97-103 Reade street, New York City, is marketing the Knowlson spring leaf spreader, which is easily operated and adjustable to any size spring. One of the qualities of the device is that it is not necessary to loosen the spring clips. As will be noted by the illustration, the tool has a screw member provided with a point. By rotating the screw the leaves are forced apart, enabling the introduction of the lubricant. The tool is made of drop forgings, nickel plated and polished, and weighs but 15 ounces. It can also be used to make a temporary repair to a broken spring.

J. & B. FUEL SAVER.

Dash Device Automatically Controlling Extra Air to Intake.

As the efficiency of the motor largely depends upon the correct proportions of fuel and air, a number of devices for regulating the supply of air from the seat have made their appearance during the past year. The principle involved is that of admitting atmosphere when it is supposed that too large a quantity of gasoline is emerging from the jet of the carburetor, and when the motor is attaining high speeds.

The majority of the devices marketed provide for manual control; that is, the operator of the car utilizes his judgment as to the amount of air required. The device manufactured by Jones & Buckoke, 1413 Michigan avenue, Chicago, differs

from conventional practise in that the air is admitted automatically and according to the speed of the engine.

The J. & B. automatic fuel saver is located on the dash and is connected by a flexible tube to the intake manifold between the carburetor and the cylinders. The dash device contains an air valve, which opens and closes according to the varying suction which changes with the speed of the engine.

When the motor is running slowly the valve is closed, but as the speed picks up, a valve member is automatically released from its seat, and allows air to be drawn into the intake manifold, the extra atmosphere being in proportion to the requirements of the engine.

MOSCO FORD WHEEL PULLER.

Provision Is Made for Variation of Treads of Hub.

Certain types of rear axles necessitate the use of a wheel puller when it is necessary to displace a wheel from the axle. The model T Ford car is one of these and, to enable the removal of the wheel without damaging it or marring the paint, the Motor Specialties Company, Waltham, Mass., has designed the Mosco wheel puller.

As will be noted by the accom-

panying illustration, it is made to be screwed on to the hub of the wheel, and a liberal sized set screw is employed to draw the wheel from the axle. One of the qualities of the Mosco is that a simple binding screw adjustment is incorporated. This adapts the device to any variation that may exist in the thread of the wheel hub, as well as eliminates danger of stripping. The Mosco is constructed of high grade material, nicely finished, and is inexpensive.

MOTOR STARTERS.

The editor of this department has received a number of letters from readers asking for information upon motor starters and lighting systems for the Ford and small machines. This subject will be thoroughly discussed in the April 25 issue of The Automobile Journal, which will be the annual overhaul and equipment number. Manufacturers of lighting and starting systems for small cars are invited to contribute data upon this interesting subject.

PYRMA ALUMINUM HEEL PLATES.

Prevent Wear of Ford Floor Mat and Are Easily Attached.

After considerable service the rubber floor mat of the model T Ford car shows signs of wear where the

operator rests his feet when driving. This is due to placing the heels on the material and the feet in a position convenient to the pedals.

The Metallic Automobile Matting Company, Rochester, N. Y., is manufacturing the Pyrma aluminum heel plates for the Ford machine, and one of the qualities of the design is that the use of screws, rivets, etc., is eliminated when attaching the plates to the matting. The Pyrma is fitted with corners, which are bent down, placed on the mat and the positions of the holding members marked. Slits are then cut in the mat, the corner members inserted and bent to clinch. It is stated that the plates can be attached in three minutes. They are moderately priced.

HOLDEN TIRE TOOLS.

Designed for Clincher Demountable Rims and the Ford Car.

The Holden Manufacturing Company, St. Paul, Minn., is producing the Holden tire tool, which is made in standard and a special form, the latter for the model T Ford machine and shown in the lower right hand corner of the illustration. The Ford tool is made for three and 3.5-inch clincher tires.

The standard is designed especially for clincher demountable rims, and it is stated that it will loosen a shoe easily, no matter if it be frozen. By turning the handle outward just past dead centre it locks, holding the bead inward, facilitating removal when the rim is split crosswise. It is adapted to 3.5 and five-inch tires, is finished in aluminum and weighs but two pounds. They are inexpensive.

MOSSBERG FORD WRENCHES.

Constructed to Remove Nuts from Cylinder Head and Hub Cap.

The Frank Mossberg Company, Attleboro, Mass., is manufacturing a number of useful tools for the model

T Ford car, some of which are shown in an accompanying illustration, these including single and double-end cylinder head socket wrenches and a hub cap member. The single-cylinder head wrench is known as the No. 620, the double as No. 625, and either of these tools makes it a simple matter to displace the nuts and replace them quickly and properly. The difficulty of reaching these nuts with ordinary tools is well known to owners. The hub cap wrench is a particularly well designed and constructed tool and like the wrenches is made of a high grade material and is inexpensive.

LIEBSON MOTOR STARTER.

Employs Explosion of Gas to Rotate the Crankshaft.

The Liebson Self-Starter Company, 412 Georgia Life building, Macon, Ga., is marketing the Liebson self-starter, which is held to be adaptable to any make of car, does not require skilled mechanics to adjust it and weighs less than 10 pounds.

It differs from the conventional types of motor starters in that it is operated by compression and explosion, the principle involved being practically the same as that of an internal combustion engine. A lever operates a small brass pump, to which is attached a specially constructed carburetor. In moving the lever backward, fuel from the main tank is drawn by suction through the carburetor into the pump.

At the completion of the suction stroke, the proper amount of air is mixed with the fuel, and the next forward movement of the lever compresses the mixture, sending it through a pipe into a distributor having as many outlets as there are cylinders to the engine. An ar-

range of valves actuated by cams makes for proper distribution of the gas, which is ignited by an electric spark.

A feature of the starter is that in forcing the charge into the cylinder there is sufficient pressure to start the crankshaft revolving, and the ignition is so timed that the explosion takes place after this movement has begun. From the above it would appear that the starter combines the compressed air and explosion methods for starting.

BARRETT 1914 JACK.

New Design Has Several Practical Features of Interest.

The Duff Manufacturing Company, maker of the Barrett automobile jacks, has brought out a new design, termed the 1914. One of the qualities of the new jack is the casting integral with the malleable iron top, an adjustable lifting member, which is of advantage in that it permits using the jack where the height is less than the maximum of the regular top. The smaller top member slides and is secured by bolts. This

construction adapts the jack to all types of machines.

The pawl points are machined all around, meshing perfectly, making for a large factor of safety, efficiency and convenience. The pawl bearings are also machined. The bearings, gears and racks are constructed of a high grade carbon steel and each jack is rigidly tested before leaving the factory. A tire tool lever is supplied with all the new styles marketed by this concern.

SIGNALLING DEVICES.

With the large variety of signalling devices offered the motorist and at very reasonable price, there is no reason why every car should not be equipped with an efficient signal, one that leaves the pedestrian no opportunity to state that "he did not hear the horn". During the past six months a number of moderately priced practical signals operated by electricity have made their appearance. These have been supplemented by mechanical types, eliminating the need of current, but operating in a similar manner and as productive of results.

ROHE MOTOR CAR BLOCK.

Designed to Extricate Machine from Mud, Etc., by Own Power.

In the spring of the year, when visiting the country sections, and especially after a heavy fall of rain,

the driving wheels of the machine are likely to become mired unless one be careful. Usually the driver has to engage a pair of horses to extricate the machine when ordinary methods fail.

The Rohe Traction Block Company, Kenmare, N. D., is marketing the Rohe motor car block, which is designed to enable a car to extricate itself out of a mud hole or other place where traction cannot be obtained. The block is approximately 30 inches long and is placed, as shown in the accompanying illustration, with a chain attached to a strap. When power is applied the wheel in revolving draws the chain and block under it, thus providing a tractive surface.

AVON AIRLESS TIRE.

Wool Felt Employed as a Material—Many Advantages Claimed.

The American Tire Company, Montello, Mass., is manufacturing the Avon airless tire, which is designed for light and heavy trucks. It is made in both flat and round treads. The tire is the result of a series of experiments with wool felt by the inventor, and it is stated that none of the desirable resiliency of the pneumatic is sacrificed.

It is pointed out that the material utilized in the Avon tire can be subjected to enormous pressure without affecting it, as it will quickly resume its normal form. Among the advantages of the construction emphasized are: Creeping is eliminated, internal friction avoided and saturation prevented. It is obvious that wool felt is not affected by punctures nor susceptible to blow-outs. For the present manufacture of Avon tires will be confined to commercial vehicles.

MOTORIZING POLICE DEPARTMENT.

City of Detroit Places in Service Car Having Special Body for Transporting Canines.

Police Commissioner Gillespie, who is in charge of the motor department of the city of Detroit, has placed in commission the new motor dog wagon, which is fitted with a body to meet the requirements of this particular branch of the service. As will be noted by an accompanying illustration the body is partitioned by lattices, providing a number of individual compartments which are available through doors at the rear and sides of the car, making for convenience in storing the canines while in transit.

The vehicle is the product of the Commerce Motor Car Company of Detroit and is the second machine purchased by the city from this company within a year. Commissioner Gillespie states that he finds it more advantageous and

Novel Motor Vehicle Utilized by Police Department of Detroit to Transport Canines.

economical to use light vehicles, in that the unit cost permits of having two automobiles at approximately the cost of one large machine.

SPRING PREPARATIONS.

Chas. E. Miller's Big Catalogue Contains Many Suggestions for Preparing the Car.

With the appearance of spring the thoughts of motorists turn seriously to the overhaul and preparation of the car for the road. This involves, if the owner does his own work, a method that is gaining many adherents, the selection of tools, supplies and those devices which economize in time and labor. Those who are not familiar with the equipment required, as well as the experienced, will find many valuable suggestions in the annual catalogue, which is issued and forwarded free upon request by Chas. E.

Miller, 97-103 Reade street, New York City.

It contains hundreds of pages illustrating and describing thousands of parts, accessories, equipment and motoring conveniences, and the use and application of each are explained fully. The house of Chas. E. Miller was established in 1896 and it now has branches in the leading cities of the country. Having specialized for years in accessories, parts, tools, equipment, etc., Mr. Miller is entirely familiar with the requirements of the motorist and trade. A postal mailed will bring a free copy of the book above referred to. All motor car owners should have a copy of this encyclopedia.

SERVICE MEN ORGANIZE.

Managers of Detroit Plants Combine with an Idea of Improving Departments.

The service managers of the various motor car manufacturers of Detroit have formed an organization which will number from 16 to 20 members, the object being to improve the service departments of the industry. It is believed that the interchanging of ideas and benefit of experiences will be invaluable.

The officers elected are as follows: President, D. H. Haselton, Regal Motor Car Company; vice president, A. B. Hanson, Chalmers Motor Company; secretary, G. O. Baldwin, Studebaker Corporation; treasurer, Virgil Oldberg, Hudson Motor Car Company.

The organization has been approved by a large number of manufacturers. Mr. Haselton states that while it is too early to say just what the scope of the organization will be eventually, he believes it to be far reaching in its aims. A general understanding of the methods of handling adjustments and claims, and a policy with respect to service departments is aimed for, and a standardization of these matters and co-operation cannot but be of benefit to both manufacturer and buyer alike. It is hoped to extend the organization to all manufacturers whether located in Detroit or not.

EQUIPPING THE GARAGE.

The purchaser of a new machine who intends to attend personally to its upkeep, will find many valuable suggestions dealing with the selection of the garage equipment in the annual overhaul and equipment number of The Automobile Journal of April 25.

FEATURES OF L. U. C. VALVE MECHANISM.

A NOVEL and interesting design of valve operating mechanism is noted in the L. U. C. motor fitted to Loeb cars, manufactured by Loeb & Co., Charlottenburg, Germany. The accompanying sectional drawing and diagram of the valve cycle are practically self-explanatory.

Showing General Arrangement of L. U. C. Valve Mechanism.

It will be seen that a poppet valve of the ordinary type is used, and is acted upon by an adjustable tappet, which does not differ materially from standard practise, but varies, however, in regard to the heel piece, which is of a distorted mushroom shape.

The design differs from conventional practise in regard to tappet valve operation in the entire elimination of the camshaft and the cams. At the side of the engine, driven by silent chain, is a valve shaft D, shown in both illustrations. This is in reality a miniature crankshaft having eight crank pins with a four-cylinder motor. Each of these pins actuates a connecting link C.

To obtain the same effect as a cam, that is, to give the necessary "dwell" to the valve in both closed and open positions, the connecting link C acts upon the heel of the tappet through the rocker B. This rocker, at one end, is pivoted to the crankcase; at the other end it is coupled up to the connecting link C.

Referring to the diagram of the valve cycle (the inlet only is shown), it will be noted that the heel of the tappet is never entirely out of contact with the rocker B, but that, during the whole of the time when the valve is closed, one end of the heel rests upon the rocker just over its pivot pin. While the valve tappet remains motionless during a large portion of the cycle of the motor, the link C continues to be moved, being coup-

led to the crankpin of the valve shaft, the free end of the rocker being moved with it.

When the time approaches for the valve to be opened, the rocker is gradually brought into a horizontal position under the heel of the tappet. There is no sudden blow of contact as with a cam, but an easy and gradual commencement of the lift. The period of "dwell", while the valve remains open, depends upon the relative shapes of the top of the rocker B and the bottom of the tappet heel, so that it is possible to simulate exactly the motion given to a poppet valve by means of cams, or perhaps to improve on it.

The advantage claimed for this simple and ingenious valve mechanism is the elimination of noise, and it would appear that, even though a valve movement be obtained similar in effect to that provided with cams on super-efficient engines, the valve gear should be almost, if not equally, as quiet as a movement giving a slow lift and drop. There is, of course, the blow of contact between the head of the valve tappet and the valve stem, but this, it is generally admitted nowadays, is not of itself productive of any noise worth mentioning, for in the average poppet valve engine any noise which exists is usually caused by the cam striking the lower end of the tappet. In the L. U. C. engine this source of noise is eliminated by what might be termed a rolling contact, which always occurs between the heel of the tappet and the rocker B.

Referring to the cross sectional view of the motor, it will be noted that under the valve shaft is provided a crescent shaped trough in which oil is retained as it is thrown transversely by the large ends of the connecting rods, and into which the valve link C dips at each revolution. A feature is the accessibility of the valve shaft.

Four Diagrams of the Exhaust Valve Cycle of the L. U. C. Motor; the Reference Letters Are the Same as in the Sectional View; Figure 1 Shows the Valve About to Open; 2, Fully Open; 3, Just Closed; 4, at Rest During Compression Stroke.

WITH THE CYCLECAR MANUFACTURERS.

Eight Concerns Making Delivery and Others Have Production Plans Well Under Way---Details of Morse Front Drive Model---Other New Designs.

CONDITIONS within the cyclecar branch of the automobile industry are rapidly assuming definite shape, although few concerns have as yet begun production on anything like a quantity basis. Several companies state that they do not intend to market machines in large numbers until they have had full opportunity for studying the situation. Among automobile engineers it is regarded as necessary to allow practically a year for the development of a car. The American cyclecar cannot be considered as quite a year old as yet, although several designers have been experimenting for much longer periods of time than others.

From what are believed to be reliable sources

Front View of Morse Front Drive Model.

it is learned that at least eight manufacturers actually are engaged in the delivery of machines, although in most instances this means that the cars are going to dealers and are to be regarded as demonstrators. The Imp Cyclecar Company of Auburn, Ind., is generally conceded to have been the first to place cars in the hands of dealers, deliveries having been begun sometime in September. Reports indicate that the present rate of production is 30 a day.

The Mercury Cyclecar Company, Detroit, is said to be producing five machines a day and it is stated that this number will be increased to 20 within a very short time. The Scripps-Booth Cyclecar Company of the same city has material ready for a large number of cars; has already

made some shipments, and expects to be producing at the rate of 20 a day this month.

In Indianapolis, the Comet Cyclecar Company is reported to have made its first shipment recently and to be in a position to begin quantity production at once. The Merz Cyclecar Company also is reported as having made several shipments to dealers, and plans are said to be well advanced toward quantity production.

The Zip Cyclecar Company, Davenport, Ia., according to Manager R. W. Phelps, is making shipments to dealers, and has its factory force well organized. The Dayton Cyclecar Company, Joliet, Ill., is reported to have shipped several machines and to have a large plant in operation. Similar reports are made with respect to the Dudley Tool Company, Menominee, Mich.

Other concerns which are stated to have production plans well underway, and to be in a position to begin deliveries in the near future, are: The American Cyclecar Company, Bridgeport, Conn., maker of the Trumbull, and the Twombly Car Corporation, New York City, Twombly.

It is probable that this list by no means includes all of the companies which are, or soon will be, in position to make delivery of demonstrating cars, at least. The reports are presented, in keeping with the announced purpose of The Automobile Journal to supply such information and facts as it is able to secure respecting this situation. It will be understood, however, that this magazine assumes no responsibility in making public these statements, but acts solely in an effort to place its readers in a position to make their own deductions concerning the ability of the manufacturers to meet the demand for cars. As a matter of fact, it cannot be expected that many machines will be placed in the hands of owners for at least another month or two.

MORSE FRONT DRIVE.

Additional Information Respecting the New Design Announced in Pittsburg.

Mention was made in the last issue of the Morse front drive car, made by the Morse Cyclecar Company, 519 South Lang avenue, Pittsburg, Penn., but little information concerning the machine was available at that time. The de-

signer is Frank H. Morse, an automobile engineer, who is stated to have produced his first successful car in 1902, and since that time to have

versal joint within the steering knuckle is in line with the steering pivot and its outer end is connected to the face plate of the hub. This permits of steering as well as driving the front wheels.

Side View of the Morse Front Drive Cyclecar, a New Product, Which Is Made in Pittsburg.

been connected with some of the largest automobile manufacturers in this country. It is not understood that quantity manufacturing has begun, although the machine shown has been subjected to severe road tests and is believed by the designer to be an entirely practicable construction.

The main feature of the Morse, which is a true cyclecar, lies in the front drive, which system is said to have been thoroughly tried out on trucks carrying loads up to 10 tons as early as 1906. It is maintained that it can be used for driving all four wheels, although this is not held to be necessary in a machine of this weight and power. The car has a wheelbase of 105 inches and tread of 36. The two passengers are seated tandem. The weight is given as 450 pounds.

The motor is a Spacke, two-cylinder, air-cooled, V type unit, with bore of 3.5 inches and stroke of 3.67. Ignition is by Atwater Kent Unisparker, six dry cells being held to be sufficient for 3000 miles of service. The carburetor is a Schebler. The transmission also is of the Spacke manufacture, a planetary type, affording two speeds forward and reverse.

As will be noted, the motor is placed in front, and a chain communicates with the planetary transmission. Another chain runs forward to the front axle, giving the same form of drive as with a motorcycle. The front axle has a solid drive shaft within the tubular axle. The wheels are pivoted on enlarged steering knuckles, the steering pivots being located in the centre of the wheel plane. A uni-

The designer states that this gives a very simple drive, highly efficient, and reduces skidding to a minimum. He adds that as long as the car is going straight ahead, which is about 95 per cent. of the time, the universal joints have no work to do, and that at low speed, when turning corners, there is not much work on the joints. He says that the solid drive to the two front wheels seems to act all right, doing away with the differential.

The springs are of the cantilever type. Brakes are applied both front and rear, those at the rear entering the V belt pulley, while the front brake acts on the planetary transmission. The wheels are of wire, carrying 28 by three-inch tires. The body is of steel or aluminum, the latter being rated at a slight extra cost, the advantage being in about 50 pounds less weight. Equipment includes a horn, three lamps and tool kit.

DETAILS OF THE ROCKET.

A True Cyclecar Which Early Came into Prominence Because of Road Tests.

One of the first American cyclecars to undergo road tests, and perhaps the first to make a long distance cross country run, was the Rocket, made by the Scripps-Booth Cyclecar Company, Detroit, which concern also produces the Packet, a cyclecar package delivery wagon fitted to the same chassis. In the latter part of September

The Rocket Tandem Model Now Seats the Driver in Front and Employs Shorter Belts.

one of these machines left Detroit for a 1000-mile tour of three states, visiting points in Ohio, Indiana and Illinois before returning to the fac-

Saginaw Cyclecar Breaking Roads in the Vicinity of the Company's Factory.

tory. Two persons were carried on this trip.

While in the main this original machine presented practically the same appearance as that which is illustrated herewith, it may be stated that the driver was located at the rear, following the example set by the Bedelia of France, and that a somewhat longer belt drive was utilized, the forward pulleys, and, of course, the jackshaft, being located immediately behind the engine in front of the forward seat. At the conclusion of the test it was stated that the belt drive had acquitted itself most creditably and that a book could be written respecting its merits.

It will be seen that the car is a tandem seater. At one time it was announced that the purchaser might have the option of front or rear location of the driver. This option does not appear in the latest catalogues. The wheelbase is 100 inches, the tread 36 and the road clearance nine. The weight is given as 750 pounds.

The motor is a two-cylinder, air-cooled, V type unit, with bore of 3.5 inches and stroke of 3.66, giving a piston displacement of approximately 70 cubic inches, which, with the weight, places the machine in the true cyclecar class. The maker rates this engine at 10-12 horsepower at normal speeds and 15 at 2600 revolutions a minute. Ignition is by the Atwater Kent Unisparker system, and carburetion by a special Schebler.

The clutch is of the disc type, embodied as a part of the special Scripps-Booth planetary transmission, which is made in a unit with the jackshaft. Front pulleys, eight

inches in diameter, take V belts transmitting energy to pulleys, 15.75 inches in diameter, on the rear wheels, and the total reduction from the motor to the rear wheels is given as 5:1. Adjustable belt tighteners are fitted. The springs are quarter-elliptic. Brakes are internal expanding, Raybestos lined, on the rear wheel hubs. The front axle is a special Scripps-Booth I beam drop forging, heat treated, and the rear axle is tubular. The wheels are of wire, carrying 28 by three-inch tires.

The body is of metal, of streamline design, with high sides and two doors on the right. The seats are 22 inches wide and 15 deep, with 30 inches leg room. Standard equipment includes the windshield, three lamps, horn and tool kit, while a patented one-man top, with side curtains and irons, and a speedometer are listed as extra.

The company states that it is in a position to deliver these cars in quantity, and invites prospective dealers to visit the factory and make every investigation as to what the company is doing.

SAGINAW ROADSTER TYPE.

Specifications of True Cyclecar Produced by Well Known Boat Manufacturer.

The Valley Boat & Engine Company, Saginaw, Mich., has been producing motor boats for a number of years, and is well known in that industry. Some time ago it was announced in these columns that this concern was to engage in the production of cyclecars, and this is the first opportunity that has been presented to illustrate the machine and call attention to its specifications. The photograph reproduced herewith shows the car breaking out roads in the vicinity of the factory in Saginaw.

The Liberty Roadster, Designed by Joseph A. Anglada, a Well Known Consulting Engineer.

The machine is a true cyclecar of the roadster type, with wheelbase of 100.5 inches, tread of 36 and road clearance of 8.5 inches. The weight is given as 650 pounds. The motor is a two-cylinder, four-cycle, air-cooled, V type unit, with bore of 3.375 inches and stroke of 3.9, being rated by the maker at 9-12 horsepower. Ignition is by Atwater Kent Unisparker. Lubrication is by splash, with pump circulation. The carburetor is an automatic float feed type.

Transmission is by friction discs, giving unlimited speeds forward and reverse. Drive from the jackshaft is by two 1.125-inch V belts of leather and steel, which are claimed to be stretchless. Both axles are tubular, 1.5 inches in diameter. Springs are quarter-elliptic, cantilever type. The foot brake is external contracting on the jackshaft, with extra large braking surface, lined with Raybestos. The friction transmission is employed in reverse as an emergency brake. The wheels are of wire, carrying 29 by 2.75-inch tires.

The machine shown is a tester, and does not present the complete equipment. The body is of the streamline design, with cowl dash. The driver is seated at the left, with centre control levers. The equipment includes a top, one-piece ventilating windshield, electric horn, two parabolic electric headlights in the front fenders fitted with dimming attachment for city driving, tail light, 60-mile Stewart-Warner speedometer, 60-ampere storage battery, tire pump, repair kit, etc.

ANGLADA'S LIBERTY MODEL.

Construction Details of Machine Designed by Well Known Consulting Engineer.

Announcement has been made in these columns of the organization of Liberty Motor Company of New York City by Joseph A. Anglada to produce the Liberty cyclecar, designed by him. Mr. Anglada is well known in the industry as a consulting engineer, inventor and designer. He is president of the company, while the other officers are: Secretary, C. S. Ackley of the McKiernan-Terry Drill Company, New York City, and treasurer, A. W. Drake, a coal operator in Hazelton, Penn., and formerly head of the Harvard Electric Company. It is stated that a permanent factory will be established in the near future, but for the present some 200 cars are to be produced in a temporary plant on Perry street, New York City.

The machine is a true cyclecar of the road-

ster type, seating its two passengers side by side. The wheelbase is 92 inches and the tread 42. The weight is about 550 pounds. The motor is a two-cylinder, air-cooled, V type unit, the dimensions of which are not stated, but the rating given by the maker is 15 horsepower at 2500 revolutions a minute. Ignition is by generator and battery, and the motor may be started from the driver's seat.

Transmission is by friction wheel engaging with the rear face of the flywheel, and four forward speeds and reverse are afforded. Final drive to the rear wheels is from the friction wheel shaft by belts. The 16-inch hand wheel is placed at the left, and the brake and change speed levers are located in the centre. The brakes are of the railway type, engaging in grooved belt pulleys on the rear wheels.

The body is practically one piece of sheet steel, and is of the so-called French torpedo type, with gunboat stern. The seats are individual, each 18 inches wide and 18 inches deep. There is a baggage compartment in the stern, 24 by 35 inches and 15 inches deep. The equipment includes a mohair top, windshield, two electric headlights and tail light, with storage battery and kit of tools.

FOREIGN MARKET CONDITIONS.

Current Reports by American Consuls to Be Placed on File at Various Cities.

Current reports by American consuls on market conditions for American motor vehicles will be placed on file by the Bureau of Foreign and Domestic Commerce according to the following schedule for examination: Chamber of Commerce, Indianapolis, Ind., March 30 to April 10; Board of Commerce, Detroit, April 13 to 24 inclusive; Chamber of Commerce, Buffalo, N. Y., April 27 to May 8; Chamber of Commerce, Cleveland, O., May 11 to 22 inclusive; branch office of the bureau of Foreign and Domestic Commerce, Association of Commerce, New Orleans, May 27 to June 13; Appraisers' Stores building, Washington and Centre streets, San Francisco, Cal., June 17 to 27 inclusive.

The reports are in manuscript form and contain much valuable information, covering 15 countries in Europe, also Canada, Honduras, Brazil, the West Indies, Peru, Uruguay, India, Japan, Arabia, Ceylon, Java, the Straits Settlements in Asia, Portuguese East Africa, South Africa, Australia, Madagascar, Tasmania and the Society Islands.

MECHANICAL NOTES FOR OWNERS.

Practical Method of Constricting and Removing a Piston Ring Expanded in a Combustion Chamber---Maintenance of a Timer---Novel Windshield Ventilator.

THE removal and replacement of pistons and rings rarely give trouble if the work is performed properly, but an exception was noted by the writer recently. The owner of the car decided to replace a pair of cylinders with new, and ordered pistons and rings for the casting. Due either to carelessness at the factory or to the pistons moving in transit, both slipped upward until their heads came in contact with the top wall of the combustion chamber. Naturally the top ring expanded and when an attempt was made to remove the pistons it was found that the ring had caught.

Owing to the limited space it was found to be impossible to insert any type of clamp to compress the ring, although several methods and dif-

Fig. 1—Utilizing Thin Metal Band to Compress Ring When Piston Head Slipped into Combustion Chamber, Preventing Removal from Cylinder.

ferent kinds of material were employed. The owner was advised by the foreman of a large repair shop to utilize piano wire, inserting it through the valve plug openings and passing it under and around the piston and ring. This method was employed by the repairman, who stated that sometimes it required considerable time to so locate the wire that it would compress the ring diametrically opposite the slot.

The owner after repeated trials with the wire gave it up, as it was found that the wire either slipped when tightened or became lodged between the ring and the chamfer in the cylinder. The problem was finally solved as outlined at Fig. 1. By making a thin strip of metal of ap-

proximately the same width as the piston ring and passing it through the valve plug openings, it was a simple matter to locate the band in the desired position; that is, diametrically opposite the slot. One person drew the band taut and exerted an upward pull which forced the ring on its seat or groove in the piston. Another person utilized a pair of screw drivers, compressing the ring at the points indicated in the drawing. With the band and screw drivers, a three-point compressional effect was obtained, and it was a simple matter to withdraw the piston back into the cylinder proper. The other cylinder was treated in a like manner and the entire operation consumed but a few minutes. Before beginning the work the ring was turned so that the slot was on top, or between the screw driver points.

WIRING COMMUTATORS.

Commutators or timers are not as generally used as formerly, for with the advent of the dual type of magneto, providing battery ignition for starting and as an auxiliary on the same set of plugs, manufacturers of motors eliminated them, although they are found on some high priced modern machines.

Timing the ignition with a commutator is **very simple**, but many owners do not understand the principles involved, and when trouble is experienced generally consult the expert. The following suggestions for timing and rewiring a commutator will be of value to the novice either in the overhaul or in case of ignition trouble on the road.

It is not necessary to locate the piston accurately in case the timer has been removed for repairs, as the method outlined at Fig. 2 C will eliminate the trouble. Assuming that the timing is correct; that is, the timer is set properly: mark a slot in the timer shaft and another on the coupling member. The two marks should coincide as shown in the drawing.

Marking the Timer.

If the timer has been displaced, all that will be necessary is to make sure that the piston of the first cylinder is on compression or about to fire. This position will be indicated by the marks referred to since the roller or other contact making member of the commutator makes

but one complete revolution to obtain the four contacts with a four-cylinder motor. To simplify matters the marks could be placed opposite or

nected. This should be done before the roller member is located.

The work of rewiring timers should be carefully performed. While the leads do not carry any high-tension current and do not require as careful insulation as the spark plug cables, they are subject to the action of oil, which breaks down the insulation. As the timer housing is rotated a certain number of degrees to obtain an advance and retard of the spark, it is important that the wires be so connected to the timer that they will not be brought into contact with each other or with metal.

The sketch at A depicts a simple method of carrying the wires and at the same time it separates them from each other. The device is shown at B and comprises a circular piece of fibre about .25 inch thick, through which are bored four holes. Both the sketches A and B show the parts marked according to the firing order of the motor, which in this instance is 1-2-4-3, and with the timer shaft rotating anti-clockwise. By marking the timer housing it is a simple matter to replace the wires.

Care of Timers.

Commutators should receive care, as their parts are subject to friction and wear. The cover should be displaced and the interior flushed with gasoline to remove particles of metal and foreign elements that collect. If a timer be examined after considerable service it will be noted that the lubricant used is much discolored. The foreign elements set up considerable resistance to the passage of the primary current and the re-

Fig. 2—Wiring of Timers: A. Numbering and Separating Leads by Disc Shown at B; C. Marks to Simplify Correct Replacement of Commutator.

in line with the contact block of the No. 1 segment of the timer.

Utilizing the Piston Travel.

If the set screws or locking nut retaining the contact lever of the timer should work loose, and no marks have been made as above described, it will be necessary to utilize the piston travel. Turn the starting crank and watch the inlet valve of the first cylinder (that nearest the radiator). The valve starting to lift will denote that the piston has begun the intake stroke and is moving downward. The crankshaft should now be rotated until the stroke is completed, and another half-turn given until the piston moves upward or completes the compression stroke. This will be indicated by the resistance in cranking. Place the piston on top dead centre. This may be determined by passing a wire through the petcocks if they are so located as to give access to the combustion chamber, or by removing a valve cap and inserting the wire through and into the chamber. Another method is to remove the crankcase, but this involves considerable trouble.

Timing by Piston.

After locating the piston on top dead centre, rotate the flywheel slightly until the piston has begun to move downward. The distance necessary will vary with the design of the motor, but .25 inch will serve in the absence of the maker's instructions. Next attach the timer, and rotate the adjustable coupling until roller of the lever is just making contact with one of the metal segments. Tighten both set screws or other locking members very tight. In doing this work it should be borne in mind that the spark lever should be fully retarded and the linkage con-

Fig. 3—Novel Windshield Ventilator Utilizing Form of Ball Bearings.

sult is that the coil units have to be adjusted to utilize more current. After cleaning the working parts they should be lubricated with a light

oil. Grease and vaseline are used, but the best results do not obtain with these heavy bodied lubricants.

NOVEL VENTILATOR.

The difficulty of obtaining a clear vision of the road when operating in stormy weather with the windshield up has been avoided in this country by the use of the rain vision type, which permits of so adjusting the upper glass as to permit of a view of the road without exposing the occupants of the front seat to the weather.

Practically the same results are obtained in the Goslett auto-ventilator, an English attachment for the windshield, a description of which was given the writer by a motorist who formerly resided in England. The device is shown at Fig. 3, the larger sketch showing its application to the windshield proper. It consists of a window which may be moved upward to obtain various openings, these, of course, being limited by the size of the window.

One of the interesting features of the device is the use of balls on which the window slides. The small sketches give an idea of the construction of the supports which are attached to the larger glass by drilling and clamping. The window is placed next to the windshield and the proper pressure is maintained by the balls. It is stated that the window is moved with little effort and that it will remain as placed without any fastening, on account of the pressure maintained. It is said that there is a large number in service and that they are generally fitted to the tonneau windshield. When fitted it is held not to detract from the appearance of the windshield. The Goslett device is marketed at a reasonable cost.

SPLICING CABLES.

If it becomes necessary to splice a high-tension cable, the wire of each section should be bared sufficiently to permit of making a good twist of the ends. The part is next soldered. As the high-tension current will take the path having the least resistance, the bare wire can be protected by covering it with some form of plastic tire cement, then wrapping the part with friction tape.

CARE OF MAGNETO TERMINALS.

To obtain maximum efficiency from the magneto its terminals and those of the transformer coil must be kept clean and tight. With the type

of instrument providing dual ignition the battery current is carried to the breaker box, where it is interrupted by the breaker mechanism, although there are exceptions as in the Simms magneto for example.

If the leads to the breaker box are loose considerable trouble may be experienced in starting on the batteries. If oil or grease has accumulated around the terminals, remove the wire, etc., and clean with gasoline, noting if any of the strands of wire are loose. All wires should be soldered to the terminals and the latter so placed that there is no opportunity for them to come in contact with the metal of the breaker housing. The writer noted a case recently where an owner was delayed over two hours trying to start the motor. The trouble proved to be a defective connection at the breaker box.

VEHICLE LIGHTING IN NEW YORK.

Highway Law Amendment Provides for Lights Outside of Cities, Etc.

An amendment to the highway law of New York State provides that all horse drawn vehicles in use on the highways, unless loaded with hay, shall carry lights at night, provided that they are in use outside of large cities where the street lights are not more than 500 feet apart. This provision, however, is expected to insure the carrying of lights at night by practically all vehicles, and is regarded as a distinct advantage toward making traffic safer in the country sections.

JUDGE FAVORS MOTORISTS.

Holds That City Council Cannot Specify Time Car Is Left Standing.

When the city council of Des Moines, Ia., enacted an ordinance that prohibited an automobile standing at a curbing more than 20 minutes, there was rejoicing by those who did not own vehicles, and consternation followed when the police arrested a number of citizens who sinned to the extent of a few minutes. When the defendants appeared before Judge Utterback in the police court he discharged them claiming, as he interpreted the law, the legislature did not delegate the city council the authority to specify what period of time a car should be left standing at a street curbing. Now the citizens owning machines have somewhat regained their composure and the advocates of the ordinance are correspondingly depressed.

THE BATTLE OF NANTUCKET.

Massachusetts Legislature Is Asked to Prohibit Motor Vehicles Entirely.

The little island of Nantucket, off the coast of Massachusetts, and a part of that commonwealth, already has a law prohibiting the use of automobiles during the summer months. No one thought of violating this prohibition during the winter months until last fall, when Clinton S. Folger, mail carrier, bought the Overland car shown in the accompanying illustration. Readers of *The Automobile Journal* are familiar with the reception tendered Mr. Folger when he arrived from the mainland with his Overland. One or two cases against him are pending in the superior court, on appeal, he having been fined in the police court.

At last Mr. Folger was forced to hire a horse to haul the car through the streets of Nantucket, but on the state roads elsewhere on the island, he has been permitted to carry mail unmolested, until now. Last month the people of Nantucket appeared before the legislative committee in Boston and sought the enactment of a law prohibiting the use of automobiles on the island at all times during the year. Prior thereto a special town meeting was held, at which of the 600 present but three voted against the measure. The result of the agitation against motor cars will be awaited with interest.

ADVERTISING WITH MOTOR CAR.

Poughkeepsie Dealer in Supplies Makes Known His Lines with Signs, Changing Them Daily.

Those utilizing motor vehicles can consistently develop advertising possibilities with them at comparatively small expense, for in regular service the machines are generally driven many miles daily, passing within the observation of many people. Motor vehicle owners realize what can be accomplished by carrying appropriate advertising signs on the cars.

Signs are comparatively inexpensive and can be changed frequently. They can be made of sufficient proportions to be read at a distance and

can be used to material profit. An instance of advertising with a machine is the vehicle owned and used by John K. King of Poughkeepsie, N. Y., who is a dealer in motor vehicle supplies. He specializes in what he knows will interest owners and drivers of motor vehicles and has become known in a business way to all residents of the city in which he is located. This form of publicity is legitimate and has been very productive.

NATIONAL TOURING WEEK.

Reeves Suggests Plan to Stimulate Interest in Touring and to Hold Event in July.

Alfred Reeves, the new general manager of the National Automobile Chamber of Commerce,

Mail Carrier Clinton S. Folger and the Only Automobile on Nantucket—An Overland.

has proposed a plan for a national touring week the last part of June or early in July, when motor clubs and trade associations throughout the country could arrange local tours. The plan has met with general approval.

It is generally thought that the industry suffers through a lack of interest in touring and that its stimulation would be decidedly beneficial. It is contended that a motor touring week would do much to give a spirit of unity to the industry and also help business.

It is proposed that the National Automobile Chamber of Commerce give a medal to the winner in each trade association and that some awards be made to winners of club tours. Some form of simplified stock car registration will be necessary for this touring week where the dealers are concerned. There may be special rules for dealers' tours and others for clubs.

 gress of March 3rd, 1879.

BUSINESS IS GOOD.

Those who had opportunity to study the business situation as reflected by the retail sales at the recent Boston pleasure car show, were impressed by the very apparent desire on the part of those who had not as yet made selection of their 1914 model to be assured that they were not too late. Undoubtedly, this same feeling may in some measure account for the record breaking sales which have been consummated at practically all of the automobile shows held this year.

Very little has been heard of late concerning those students of financial conditions who were loud in the prediction a few months ago that the automobile industry had reached the high tide of its development. Prospective purchasers

who were counselled at that time to await the temptingly low prices at which cars would be offered as a result of the many failures which were about due, have had occasion to learn that the manufacturer already was offering more car value for the money than ever before, and that instead of receiverships for the many, even those receivers which had been appointed were soon to be replaced by reorganized companies better capable of serving the public.

As a matter of fact, while it is confidently expected that the total output of the American automobile industry this year will exceed that of any previous year, there is much reason for believing that a car shortage will exist before the season closes. Many concerns already have contracted for the disposal of practically their entire product. This means, of course, that it has been placed with dealers. There is nothing wrong with the automobile industry. Those who thought there was were simply mistaken.

CALIFORNIA AND MICHIGAN.

It is surprising to note the difference of opinion that may exist in the minds of those who are called upon to decide as to the constitutionality of motoring laws. It is hardly more than a month since the supreme court of California handed down a decision in which it held that even if the state were attempting to secure revenue under a law which was described as a licensing measure, the law would be valid. Now comes the supreme court of Michigan, which holds that the law in question in that state is invalid because it seeks to secure revenue while purporting to be a licensing measure.

The time must surely come when this matter must be decided by the United States supreme court. Either the motorists have constitutional rights which are being violated, or they have not, and it would appear that they should be in a position to know definitely. Mississippi, Ohio and Michigan have decided the proposition one way, and California another. There appears to be no opportunity for a definite determination of the point without appeal to the federal court. And when the matter is taken up to that tribunal, it ought to include every phase of the situation, so that the point may be determined once and for all.

QUALITIES OF DIESEL OIL ENGINES.

Possibilities for Adoption for Pleasure and Freight Vehicles, by Overcoming Difficulty of Starting and Increasing Its Flexibility---Value of Fuel Pressures.

*By Eric W. Walford.

IT IS held by many that the fuel problem would be largely solved if the Diesel engine could be produced in small sizes suitable for service

Fig. 1—Sectional Diagram of Diesel Engine.

with the motor vehicle, on account of the ability of this engine to utilize heavy grades of fuel. The advantages of the type are: The ability to use cheap and easily obtained fuels, economy of operation and the elimination of the carburetor and magneto. Some of the disadvantages of the Diesel engine are:

High cylinder pressures necessitating great strength and weight, lack of flexibility, difficulty in starting and accurate measurement of the fuel.

Before discussing the above features and the possibility of overcoming these disadvantages so as to render the Diesel engine practicable for motor car work, it may be well to describe the method of operation of the engine, with the aid of the drawing at Fig. 1, which is merely diagrammatic, but represents the chief essential features.

Operation of Diesel Engine.

It will be noted that the compression space is extremely small, and that, between the two main valves, the inlet and the exhaust, is arranged a fuel valve. Driven by the engine is a pump which supplies air to an air cylinder. The engine illustrated operates on the four-cycle principle, but the Diesel principle can be applied to two-stroke cycle engines also. It is assumed that the engine has exhausted gas through the exhaust valve in the ordinary way and that the piston is about to descend. The inlet valve in the cylinder head is then opened and air alone, usually at atmospheric pressure, is drawn into the cylinders. (Sometimes this air is at a pressure above that of the atmosphere.) On the upstroke of the piston this air is compressed until, at the top dead centre, the pressure is about 500

pounds to the square inch. (In the ordinary motor car gasoline engine the pressure rarely exceeds 75 pounds the square inch.)

At the top dead centre the central or fuel valve opens, admitting fuel and compressed air. Prior to this the space around the fuel valve has had supplied to it a small quantity of oil which forms the fuel. Directly the fuel valve opens, air, compressed to a pressure of more than 500 pounds a square inch, is admitted through the fuel space and the now open fuel valve, injecting the oil from the fuel space into the combustion chamber in the form of a spray.

Compression Temperature.

The air in the combustion chamber being at a pressure of about 500 pounds to the square inch, the consequent temperature is sufficient to produce ignition. The oil as it enters the combustion chamber therefore burns, and this combustion is maintained throughout a varying portion of the power stroke, say the first quarter, when the engine is running at full load. The supply of fuel and extra air is terminated by the closing of the fuel valve. The piston, therefore, descends under the pressure of the combustion above it, until towards the end of the stroke the exhaust valve opens as usual, and on the upstroke the products of combustion are exhausted. The same sequence is then repeated.

A small pump arranged at the side of the engine maintains the supply of compressed air necessary for injecting the fuel, and compressed air is also as a rule used for starting the engine, but the mechanism employed is omitted from the drawing to simplify it.

Fig. 2—Okill's Starting System for Diesel Engine.

*Extract from The Autocar.

From the high temperature of the air in the combustion chamber it is clear that almost any finely divided fuel will be ignited. In addition to petroleum oils, creosote and tar oils can be used, which can be obtained in practically any country, and it has been suggested that coal dust could be employed, and, theoretically, there is no doubt it could, but the practical difficulties are so great that experiments with this fuel have never proved a success. The fuels that can be utilized are all extremely cheap in themselves, and, furthermore, this engine does more work to a gallon of fuel than does the ordinary gasoline, kerosene or gas engine, so that the economy of running is still further increased. Carburetor and magneto troubles are non-existent, but in place of these there are the air pump and the air bottle. So much for the advantages of the engine, which are particularly potent where the en-

Fig. 3—Suggested Method of Fuel Feed for Diesel Engines Which Might Be Adapted to Automobiles.

gine is of large size and used for continuous running.

Limiting Factors.

It will be readily understood that the pressures in the cylinders are extremely high, with the result that the cylinders and all moving parts must be correspondingly strong. This means great weight, and the weight of the reciprocating parts assists in limiting the speed of the engine, although there are more important limiting factors. Similarly, the engine will not run very slowly, so that the range of speed is very small. This certainly applied to the first gasoline engines, but everybody will agree that the modern automobile engine will operate at a sufficiently wide variation of speed, so that there is hope that the same improvement may be effected in the Diesel engine. To raise a compression of 500

pounds to the square inch it is clear that hand starting is impossible, but manual starting has been replaced on the motor car by the electric and other forms. However, considerably more power would be required to start a Diesel engine than an ordinary motor of the same size.

Starting Method.

The more recently patented arrangement shown at Fig. 2 is interesting as suggesting one method of overcoming this difficulty. Here the engine operates on the ordinary Diesel principle, but when the sleeve between the piston and cylinder walls is lowered, a port in the left hand side of it is brought opposite the combustion chamber, putting this in communication with a valve pocket. By this means the combustion space is considerably enlarged, so that the compression normally used on gasoline engines can be obtained. This valve pocket contains a spark plug and an inlet valve from which gas can be drawn from an ordinary gasoline carburetor. With the sleeve in the operating position the engine can work on the ordinary Otto cycle, using gasoline vapor. Directly it is well started the sleeve can be raised so as to cut off the valve pocket, allowing the engine to operate on the Diesel principle.

Varying Speed.

Accurate measurement of the fuel supply is of very great importance, and the power is varied by varying the period during which injection of the fuel occurs. The quantity of fuel supplied at each stroke is small even with comparatively large stationary engines. With an engine of four-inch bore and five-inch stroke, assuming the fuel pump to be five mm diameter, a stroke of only 3.1 mm would be required when the engine is running under full load, and under light loads the stroke would be only about three-quarters of a millimeter. This shows that the ordinary fuel feeding system would have to be considerably modified.

It is not suggested that attempts have not been made to use Diesel engines for motor car work, as Dr. Diesel himself co-operated with Sulzer Bros., Zurich, in experimenting with a Diesel car, but without practical success. The work is now in the hands of the Delaunay-Belleville Company, in Paris, and before the late Dr. Diesel died he expressed great hopes for the future of his device in automobile development, and anticipated seeing a Diesel car in which all minor operations, such as gear changing, brake application, etc., were effected pneumatically.

Factor of Fuel Supply.

As the pressures inside the cylinder are so extremely high, much difficulty is experienced in

preventing leakage. This would be increasingly difficult in small engines in the hands of unskilled operators. The chief difficulty standing in the way of the adoption of the Diesel engine for motor car work is in measuring accurately the very small quantity of fuel required and varying the supply as the call for power varies. A variable delivery pump is an easy matter to design, but it is very difficult to make such a pump supply a minute quantity of liquid.

The application of the Diesel engine to motor cars is dealt with at some length in a German magazine, *Allgemeine Automobil Zeitung*, of December, 1912. One method of overcoming the difficulty described therein is shown in Fig. 3, which depicts part of a cylinder head with a central fuel nozzle, which is of the open type. Just prior to the compression stroke the needle valve opens and a small quantity of fuel, under gravity or slight pressure, is caused to enter the open nozzle, the quantity admitted being determined by the period of opening of the needle valve. The nozzle contains perforated discs which impose a tortuous path on the fuel so that it does not enter the cylinder during the compression stroke. At the end of the compression stroke the air valve opens and compressed air scavenges the nozzle, blowing the finely divided fuel into the combustion chamber. In this case a single and comparatively large fuel pump for a number of cylinders is used, and the amount supplied is controlled by varying the movement of the needle valve of each cylinder.

As Applicable to Motor Cars.

The difficulties standing in the way of the development of this engine for motor car work are therefore mostly practical ones, and when the extraordinary advance that has been made in the construction of ordinary automobile motors is considered, the future seems hopeful. By the use of chrome and vanadium steels it would seem possible to make the parts of the required strength with comparatively low weight, rendering the engine practicable for industrial cars at any rate. The pressures might be further lowered by heating the air so that the compression would not have to be so high to obtain the necessary ignition temperature. The lack of flexibility might be overcome by combining with the engine a simple form of electric transmission system, and the transmission system itself might provide an electric starter. Doubtless these features introduce practical difficulties of their own, but as the matter is in the hands of the Delaunay-Belleville Company, it is expected that in time a Diesel car will be on the road.

"SAFETY FIRST" BOOKLET.

B. F. Goodrich Company Issuing Data on Rules of the Road Which Will Be Mailed Free.

In line with their policy of supplying motorists service, the B. F. Goodrich Company, Akron, O., have issued a booklet, "Rules of the Road". The purpose is to further the "Safety First" movement by placing valuable hints in such concrete form that they can be quickly mastered by the motorist.

Both new and experienced operators will appreciate the information contained in the booklet as it gives in a clear, concise manner, many new regulations which are generally acquired by the new driver by experience. Rules governing street traffic, such as passing, turning, stopping and starting are included, also data on precedence on right of way, speed laws, respective rights and duties of operators and pedestrians, lights, etc.

Chapters are devoted to the care and repair of tires, how to secure the Goodrich touring service, road marking service, good roads and how to obtain the benefits of the Goodrich

"Rules of the Road", Booklet Issued by B. F. Goodrich Company.

service station. The booklet is replete with useful and practical information and dealers who wish to supply their customers can obtain free copies of the brochure by writing the company. The booklet will also be forwarded to motorists by writing the B. F. Goodrich Company, Akron, O. It is nicely printed.

OVERHAULING THE MOTOR CAR.

Attention is specially directed to the April 25 issue of *The Automobile Journal*, which will be the annual overhaul and equipment number. An effort will be made to present descriptions and illustrations of such equipment making for economy of time and labor. Manufacturers' data must be in the hands of the editor not later than April 18 to insure its publication.

WITH THE MOTORING INTERESTS ABROAD.

Swedish Winter Trials Marked by Use of Alcohol as Fuel---Interesting Successful Freak Car Made in Germany---Other Automobile News from Foreign Lands.

ADDITIONAL interest attaches to the winter trials held in Sweden recently from the fact that four of the cars taking part were equipped to burn alcohol as fuel. These were a Minerva, Scania-Vabis, Opel and Hupmobile. The two first named finished the journey from Stockholm to Gothenburg and return, a distance of 790 miles.

Shortly before the holding of the trials, N. P. Mathiasson, director of the Reymersholms spirit factory, who has been encouraging practical experimentation with this fuel for some time, presented a trophy to be awarded to the car making the best showing on alcohol. The trophy appears to have been won by the Scania-Vabis, a car which is the product of a Swedish manufacturer.

erva-Knight, this being the third trial in which this combination has secured the trophy. The Gothenburg cup went to an N. A. G., this being the chief award for small cars. The best time in the hill climbing test was made by a Cadillac.

DETAILS OF THE PHANOMOBILE.

Interesting Machine Described by a British Owner as a Successful Freak Car.

An accompanying illustration presents the Phanomobile, a three-wheel motor vehicle, made in Germany, which is described by its British owner as a successful freak car. It is stated that machines of this type have been produced in Germany for eight or nine years, although, of course, they have differed in the detailed construction.

This model is fitted with a four-cylinder, air-cooled engine, the four cylinders of which are cast singly. This motor has a bore of 74 and stroke of 90 mm (2.9 by 3.5 inches), and is rated at 12 horsepower. It is mounted above the pivoted front wheel, at right angles to the direction of motion. The carburetor and fuel inlet are behind the cylinders, where they are held to be protected and to be in such position as to facilitate vaporization. The exhaust is in front. Ignition is by Bosch magneto and cooling is by the two fans shown.

This motor drives to the front wheel, by means of a two-speed transmission and two short chains. The gear ratios are 4:1 and 11:1. The high speed is said to give 40 miles an hour and the low speed 15. Steering is by tiller. Two sets of brakes are fitted and this owner declares that the springing is all that could be desired in any car. Indeed, he says he intended to fit a set of J. M. shock absorbers when he bought it, but has decided that this would prove entirely unnecessary. He adds that he has thus far secured 4800 miles from the driving tire and about 30 miles to the gallon of fuel on very hilly roads.

Phanomobile, Described by Its British Owner as a Successful Freak Car.

According to the Stockholm Dagblad, the Minerva car behaved well throughout, with the exception that the carburetor had to be cleaned on two occasions, and the stops thus necessitated spoilt an otherwise clean score. With the exception mentioned, the engine worked excellently and appeared to do practically well on the hills, where it was among the best performers. The Hupmobile was fitted with a supplementary tank containing gasoline, which was used for starting and until the motor had developed some initial heat before turning over to alcohol. No statement is made as to the reason for its failure to finish.

The Winter cup, premier award in the large car class, went to Hans Osterman in a Min-

CAR LIGHTING COMPETITION.

Eisemann Design Takes Second Prize in Electric Division of Belgian Tests.

A car lighting competition was conducted recently by the Association Automobile de Belgique in Belgium, the makes of lighting equipment being divided into classes: First for electric, second for acetylene and the third for other systems. There were seven entries in the first class, six in the second and two in the third.

The awards were made on a basis of 300 points, this maximum being distributed as follows: Power of the headlights, ascertained by testing their ability to illuminate, so as to make them reasonably legible at night, from a given point, different sized figures on a notice 164 yards distant, 100 points; regularity of operation and facility for repairs and recharging, 50; ease of installation and general simplicity, 50; facility of upkeep and accessibility, 25; elegance of design, ease of cleaning and minimum space occupied, 25; low price, 25. The sets to be tested were required to include two headlights, two side lights, a tail light and a dash lamp.

Awards were made as follows: Electric—Willocq-Bottin, 271 points; Eisemann, 254; Magicienne, 233; C. A. V., 211; Rubis, 210. Acetylene—Lucidus, 221 points; Willocq-Bottin, 211; Polaire, 209. Other systems—B. R. C., dissolved acetylene, 254; Willocq-Bottin, oxy-gasoline, number of points not stated.

EMPIRE IN MEXICO.

Experiences of American Automobile Men on Recent Trip to Troubled Country.

An accompanying illustration shows an Empire car, made by the Empire Automobile Company, Indianapolis, Ind., about to enter Mexico at Tia Juana, in charge of Harlow Hyde, advertising manager for the company, and William H. Nolan, a resident of San Diego, Cal. The trip into Mexican territory was made as a continuation of a transcontinental tour, and the experiences of the party, although mild to an extreme when compared with those of other Americans who have visited that troubled country recently,

were such as to rob the event of much of its pleasure.

Upon reaching the boundary the party was informed that it must leave all fire arms behind. This injunction having been complied with, application was made for permission to take a few snap shots of points of interest. This permission was granted, accompanied by an injunction not to take pictures of the federal fort.

Mr. Hyde acted as camera man, and, after taking pictures of a few inoffensive objects, he climbed back into the car with the camera open. The car was approaching the fort, when one of the members of the party recalled that it was a criminal offense to expose a camera within 100

Empire Car and Party of Americans About to Cross the Border into Tia Juana, Mexico.

yards of the fort. Less than 40 feet separated the machine from the fort when this situation was realized. The immediate presence of soldiers spurred the man at the wheel to give the Empire one of its most strenuous speed tests in reaching the American side of the border.

FRENCH IMPORTS AND EXPORTS.

Report for 1913 Shows United States Sales Were Nearly Twice Its Purchases.

Interesting figures are revealed by the annual report of exports and imports made public by the French government for the year 1913. The exports to the United States fell off very materially, and this was true to some extent with respect to Great Britain and Germany, but those to all other countries were increased.

The value of exports for the year were: To Great Britain, \$10,671,768; Belgium, \$7,396,402; Algeria, \$4,403,102; Germany, \$3,978,888; Argen-

tina, \$3,323,653; Brazil, \$1,229,679; Spain, \$1,316,839; Russia, \$1,263,764; Italy, \$1,125,769; Switzerland, \$920,801; United States, \$614,319; all other countries, \$7,148,797; total, \$43,893,797.

The imports into France, excluding those to Morocco, Algeria and other protectorates and possessions, amounted to \$3,860,000. Great Britain sent \$1,220,655 worth of cars; America, \$1,096,859; Germany, \$529,241; Belgium, \$441,970, and Italy, \$323,854.

BERLIN SHOW PLANS.

German Manufacturers Planning for Race Meet During Week of the Display.

It would appear that every effort was to be made to attract and retain the interest of the German people during the progress of the Berlin show in October. Not only have the automobile manufacturers of that country arranged to erect a special building for the display, but it is now planned to hold a race meet during the same week.

Thus far the plans are in a tentative state, merely, but it is suggested that a special track be built along the railway leading to Potsdam. The two straightaways are to be about six miles in length. At one end the track is to pass under the railway, and at the other, over it, with a side sweeping curve at each end. Thus the entire circuit would be a trifle over 12 miles.

GASOLINE IN BULK.

Great Britain's Change of Plans Makes Business Good in Kindred Lines.

As was stated in these columns recently, the motorists of Great Britain have been considering the purchase of gasoline in bulk, instead of in tins as in the past. British motoring prints have been advising their readers to give the new plan a thorough trial, as it is believed that the cost of fuel can be reduced very materially in this manner. One of the results has been that dealers in storage systems, largely of American manufacture, have been doing a splendid business during the past few weeks.

Now that most dealers in petrol or motor spirit, either of which terms is taken to mean gasoline, have been supplied with storage tanks and many motorists have followed their example, the large fuel companies are laying plans to meet the demand for their product. The British Petroleum Company, Ltd., is said to have placed or-

ders for some 120 or 130 motor trucks with tank wagon bodies for making deliveries in all sections of the United Kingdom, a few of which already have been delivered. The Bowring Petroleum Company also has purchased a large number of such wagons.

Those supplied to the former company are of the Halley and Albion makes, each with 1000-gallon tanks mounted on four-ton chassis, the tanks being divided into three compartments for different grades of fuel, oil, etc. The Bowring company is using Dennis five-ton chassis, with tanks of a similar construction.

NEWS NOTES FROM ABROAD.

It is understood that new crude petroleum fields have been discovered in South Africa, which are expected to yield large quantities of crude oil. The find is located in a district where oil shale has been mined, yielding 85 gallons of crude oil to the ton. It is stated that the product is within easy access to eastern ports, and British motorists are exceedingly hopeful that the discovery will have an important bearing upon the price of gasoline in the near future.

The maker of the Mercedes car announces that it will shortly place in the market a new 28-95 horsepower sporting chassis, equipped with the six-cylinder aeroplane engine, which recently created a world's non-stop flying record of 16:20:00. This motor has a bore of 165 mm and stroke of 140 mm (4.13 by 5.5 inches).

The Royal Automobile Club of Hungary will hold an international competition for touring cars, to be known as the circuit des Carpathes, May 24-31. The machines will start from and finish at Budapest.

The Ford Motor Company has secured a verdict against an agent in London, which establishes its right to fix a minimum price at which its cars may be sold in that country.

The Car, a British motoring print, declares that there are at present 245,907 automobiles registered in the United Kingdom, of which 18,000 are commercial vehicles.

TRENTON HONORS PULLEN.

Winner of Grand Prize, and Mechanician, Given Watches and Banqueted by Citizens.

Eddie Pullen, who drove the Mercer car to victory in the Grand Prize race at Santa Monica, Cal., was given a banquet by the citizens of Trenton, N. J., in honor of his winning the big event and being the first American driver to successfully pilot an American made car in it. Pullen and his mechanician, Andrew Vollman, were both given solid gold watches of Trenton make, also fobs containing a duplicate of the seal of the city, and enamelled in the city colors. An immense parade, headed by Pullen in the winning Mercer, was one of the features of the celebration. Prizes were awarded for the best decorated automobiles and motorcycles. At the conclusion of the banquet the Grand Prize Cup was presented to the Mercer Automobile Company by an official of the Automobile Club of America.

CARS CARRY EXPLOSIVES.

American Glycerin Company Uses Fleet of Specially Constructed Motor Vehicles.

The oil fields of Oklahoma include a large area of country that has been little developed. When wells have been drilled they are generally in localities sparsely inhabited, which necessitates carrying material and supplies sometimes long distances, frequently over country that has hardly a trail, and haulage is not only difficult, but considerable time is required.

After wells have been drilled it is occasionally necessary to explode nitroglycerine in them with a view of starting the flow of oil, and for this reason considerable quantities of this high explosive are carried about to the different places where the work is in progress. To do this work with horses is costly and dangerous, and for this reason the companies that manufacture and distribute nitroglycerine have found it advisable to use vehicles that would be more thoroughly under the control of the driver, as well as having long mileage. That is, they have taken kindly to motor vehicles, which have been specially equipped so that the explosives may be carried without danger.

The American Glycerin Company, with headquarters at Battersville, Okla., has now in use five Adams 3000-pound wagons, which have been built expressly for this work. The machines have 42-inch wheels, which gives good clearance on the rough roads and cross country hauls, and the chains are enclosed to prevent wear and to avert danger. The bodies are of the express type, but are fitted with special boxes that have covers that may be locked, and are divided into compartments, each of which will carry a single can. The capacity of each wagon is 720 quarts. With loads that have sufficient explosive energy to devastate a large area of territory, these machines are driven hundreds of miles each month, covering rough country, in all kinds of weather, and giving the best of satisfaction.

ARMORED TRUCK IN WAR.

Mexican Constitutionalists Under General Villa Utilize Two-Ton Steel Clad Machine.

The Mexican constitutionalists, of whom General Villa is regarded as the chief, are now using a two-ton Mack chassis, which has been fitted with steel armor and adapted for use on rails or ordinary roads. The wheels are armored

so that they cannot be damaged by rifle fire, and the body is constructed of sheet steel with an entrance at the rear, this resembling a conventional building because of the straight walls and slanting roof, while the hood and radiator are protected by a dome that drops nearly to the axle and carries the lamps.

The chains are shielded by aprons mounted on the sides of the body. The wheels are so built that in comparatively little time they can be changed for either road or rail propulsion. The machine is equipped with machine guns and these and the arms and ammunition are carried within the body.

AS AFFECTING RAILROADS.

Boston Car Accountant to Deliver Lecture Before Electric Vehicle Association of America.

Fred A. Hortter of Boston, car accountant of the Boston & Maine railroad system, who has given his subject careful study and can speak with experience and knowledge from the viewpoint of the railroad corporation, will deliver a paper on "The Effect of Power Wagon Operation on Terminal Freight Congestion" before the Electric Vehicle Association of America at the headquarters at 29 West 39th street, New York City, on the evening of April 24.

Mr. Hortter's observation covers a long period of time and the paper will be of much practical value, for it will deal with the aspect of the railroads and will present conditions as generally realized by transportation companies. From this point of view the estimate of the influence of the use of power wagons will be extremely interesting, and will undoubtedly be valuable for all persons shipping or receiving freight, for the possibilities for relief of congestion at terminals will mean a great deal to every business man. The subject will be approached from an operating viewpoint and with a purpose of suggesting relief from existing conditions, rather than advocating the use of any particular type or form of vehicle. Officials of the various railroads and steamship lines have been invited to be present, as well as representatives of different civic bodies.

The purchaser of a new machine who intends to attend personally to its upkeep, will find many valuable suggestions dealing with the selection of the garage equipment in the annual overhaul and equipment number of The Automobile Journal of April 25.

CORRESPONDENCE WITH THE READER.

Adjusting Overland Oiler—New Reader, Boston.

I purchased a second hand Overland model 69 recently and, while I am fairly familiar with the motor, do not understand the method of cleaning and adjusting the oiler. I was told how to increase or decrease the amount fed to the cylinders, but would appreciate an explanation of the workings of the oiler.

The oiler employed on the model 69 Overland is mechanical, and at Fig. 1 is shown a sectional view of it with the components lettered. It will be noted that it consists of a yoke shaped member, the horizontal section of which rests on a cam. The last named member is actuated by the camshaft. This cam is so mounted that when it rotates it lifts the yoke, to which is pivotally attached a plunger. A spring returns the plunger to its seating. In the illustration the yoke is shown raised.

Fig. 1—The Model 69 Overland Lubricator.

A check plunger is fitted in the feed tube, its function being to control the lubricant which is forced past it by the descent of the plunger. The amount or quantity of oil forced past the check plunger depends upon the stroke or displacement of the plunger proper. If the plunger is moved downward, by screwing down the adjustment nut the stroke is decreased, as is the supply of lubricant. Raising the plunger increases the supply.

This type of oiler is very satisfactory and will not give trouble if clean oil is used. Foreign elements have a tendency to clog the feed tube and should this occur it will be known easily by the plunger remaining up. The plunger moves up slowly, and drops suddenly, as will be noted by watching it when the motor is operating.

Horsepower Rating—N. A. Nelson, Missionhill, S. D.

Please explain in your columns at your earliest convenience, what the S. A. E. and A. L. A. M. ratings are and wherein they differ. If the methods of calculation are not too intricate would like to have you explain them both quite fully.

The S. A. E. and A. L. A. M. ratings are the same and the horsepower is based upon the bore,

the stroke not being considered. To figure the horsepower, square the bore, multiply the result by the number of cylinders and divide by 2.5.

For example: A four-cylinder motor having a bore of five inches and stroke of seven would be figured as follows:

$$5 \times 5 = 25 \times 4 = 100 \div 2.5 = 40.$$

The figure 25 represents the square of the bore, which is multiplied by the number of cylinders, which in this instance is four, and the product 100, divided by 2.5 is 40, the horsepower. The S. A. E. rating is based on an assumed piston speed of 1000 feet a minute. The subject of S. A. E. and manufacturers' ratings was explained in the March 25 issue.

Areas of Circles—Repairman, New Britain, Conn.

Some time ago you published a table giving the circumferences and areas of circles. Will you kindly forward a copy of the book to the address enclosed?

The files for the date mentioned are exhausted, but the data referred to are reproduced in the table at Fig. 2.

Naphtha—Information, Bangor, Me.

What is naphtha? Are naphtha and gasoline the same? Which wheel lifts from the ground in turning a corner at high speed and what is the cause? What is the mean effective pressures of motors?

The term naphtha covers a wide range of the distillates of petroleum. It is usually refined to a point of slightly lower specific gravity than gasoline.

The inside wheels of a machine have a tendency to lift when rounding a curve at speed. If the machine does not skid, which is due to centrifugal force, produced by a change in the direction of motion, the tendency is for the car to turn over outwardly.

The mean effective pressure in standard vehicle motors is about 71 pounds the square inch. This pressure has increased since the beginning of the automobile industry, but in a lesser proportion than the speed. It varies with the size of the motor. Thus, in a current type of motor having cylinders with a 2.4-inch bore and stroke of 4.8 inches, it attains about 57 pounds the square inch. In a motor having a bore of 3.2 inches and stroke of 5.2 inches, it is about 71 pounds the square inch, and in a motor having a bore of 4.4 inches and stroke of 5.6 inches it is about 85 pounds, all other conditions being equal. This is at 1000 revolutions a minute. The mean effective pressure increases as the result of

increased compression. It decreases as the number of revolutions a minute increases.

Tire Troubles—New Owner, Indianapolis, Ind.

Being a new owner and a subscriber to your book, I am naturally interested in anything that is going to help me in the upkeep of my machine. I hear a lot about care of tires and would like to know what are the principal causes of their deterioration.

According to figures compiled by a prominent tire maker, the result of investigations in several thousand repair jobs, the greatest causes of trouble are insufficient inflation and perforations; that is, leaving out the factor of normal wear and tear, which is estimated at 37.1 per cent. It is figured that 29.4 per cent. of trouble

pressure every few days with a gauge, which is inexpensive and much cheaper than a new casing. In fitting a new shoe and when inflated to the normal standard, it should be borne in mind that it will stretch and that it will be necessary to test the pressure and maintain it to that recommended by the maker until it has become what is known as "set".

Go over each tire daily and if any cuts exist have them vulcanized or repaired. Portable types of vulcanizers are not only practical and moderately priced, but are easily operated. There are several preparations for mending cuts and these may be obtained from any supply house. In-

Fig. 2—Circumferences and Areas of Circles Up to and Including Diameters of 13 Inches.

is primarily due to perforations by nails, stones and pieces of iron. As a result water penetrates to the fabric, which deteriorates rapidly.

It is figured that 17.3 per cent. of tire troubles is due to insufficient inflation. A shoe should be inflated to the pressure recommended by the maker, and the pressure varies according to the size of the casing. When a tire is run improperly inflated the fabric is more susceptible to shocks and stresses, and in time the plies of fabric separate, paving the way for the inevitable blow-out.

Some owners inflate their shoes to the proper pressure when replacing a shoe, but fail to maintain the pressure. It is a good plan to test the

structions on the care and maintenance of tires and inner tubes may be secured from the branches of the various tire makers.

Spring Lubrication—Reader, Kansas City, Mo.

Is there any advantage in lubricating the leaves of a spring and what is the best lubricant and how should it be used?

All components of a chassis subject to friction should be lubricated. Much of the hard riding qualities of a machine that has been in service for some time are due to rust and foreign elements on the bearing surfaces of the springs.

While it is possible to use a spring spreader,

several types of which are marketed, for opening the springs sufficiently to permit of inserting a lubricant, the better method is to disassemble the spring. This will require a rugged clamp or a vise. The spring is displaced from the machine, placed in the vise and the jaws of the latter set up near the centre bolt. The latter is then removed and the vise opened gradually. The bearing surfaces of the leaves should be thoroughly cleaned and, if the surfaces are rough, smoothed with emery paper.

Next prepare a mixture of powdered graphite and oil. Use enough of the latter to make a thick paste and spread it over the bearing surfaces, then remove the surplus material with a cloth. Sprinkle a little of the dry graphite over the bearing surfaces and reassemble the leaves. The graphite will not only reduce friction to a minimum, but it will resist the action of water. It is surprising what a difference will be noted in the riding of the car after springs have been treated in this manner.

Millimeters Conversion—A. W. S., Danbury, Conn.

In automobile news I see very frequently the bore and stroke of cylinders given in millimeters. How is a millimeter converted into our measurement of inches?

The equivalent of a millimeter in inches is .03937. To obtain the bore and stroke of a motor when dimensions are given in millimeters, it is a simple matter to multiply the given millimeters by .03937.

Carburetor Floods—Information, South Bend, Ind.

I have a Schebler carburetor, model L, and am troubled with its flooding. What is the cause and how can it be remedied?

Two general causes of a carburetor flooding are dirt in the needle valve and a leaky float. The first named member is actuated by the float and controls the flow of fuel to the float chamber. When dirt or foreign elements are in the fuel, the valve will not seat properly, and fuel continues to flow into the float chamber, flooding it.

The float utilized on the Schebler is cork, and it is possible that the gasoline penetrates the pores of the material, causing the float to become impregnated with the liquid, thereby adding to the weight of the float. The last named is coated with shellac. If the float is suspected of being too heavy, remove it from the carburetor and dry it thoroughly, then give it a coat or two of good shellac. It is a good plan to test the action of a float to note its position in the float chamber, changing it if necessary.

S. A. E. COMMITTEES.

Meetings of the Groups Include Discussion on the Electrical Equipment of the Motor Car.

The following division chairmen have been appointed by the chairman of the standards committee of the Society of Automobile Engineers, Henry Souther, and these executives will arrange the meetings of the groups during the coming year: Aluminum and copper alloys division, William H. Barr, Lumen Bearing Company; ball and roller bearing division, Howard Marmon, Nordyke & Marmon Company; broaches division, C. W. Spicer, Spicer Manufacturing Company; carburetor fitting division, G. G. Behn, Hudson Motor Car Company; commercial car wheels division, William P. Kennedy, consulting engineer; data sheet division, B. D. Gray, Hess-Bright Manufacturing Company; electrical equipment division, A. L. Riker, Locomobile Company of America; electric vehicle division, J. R. Coleman, Atterbury Motor Car Company; frame division, J. G. Perrin, Lozier Motor Company; iron and steel division, Henry Souther; lock washer division, J. E. Wilson, National Lock Washer Company; miscellaneous division, J. G. Utz, Perfection Spring Company; motor testing division, J. O. Heinze, Northway Motor & Manufacturing Company; nomenclature division, Arthur B. Cumner, consulting engineer; pleasure car wheels division, Henry Souther, consulting engineer; research division, David L. Gallup, Worcester Polytechnic Institute; seamless steel tubes division, H. W. Alden, Timken-Detroit Axle Company; springs division, Harold L. Pope, Pope Manufacturing Company; truck standards division, William P. Kennedy, consulting engineer.

The standards committee will meet April 7-9; research division, April 21; electrical equipment division, May 5; ball and roller bearing division, May 12; motor testing division, May 14.

OVERHAULING THE MOTOR CAR.

Attention is specially directed to the April 25 issue of The Automobile Journal, which will be the annual overhaul and equipment number. An effort will be made to present descriptions and illustrations of such equipment making for economy of time and labor. Manufacturers' data must be in the hands of the editor not later than April 18 to insure its publication. Lighting and motor starting systems for small cars will be featured.

MERCER TEAM PICKED.

Pullen, Bragg and Wishart Will Represent Trenton Company at Indianapolis, May 30.

As anticipated, the Mercer Automobile Company of Trenton, N. J., has entered three cars in the annual 500-mile International Sweepstakes, to be held at Indianapolis, May 30. That Pullen and Wishart would pilot was known, but the selection of the third driver was not announced until recently, when it was stated that Caleb Bragg would complete the trio.

Bragg, who has been in Europe during the past few months, cabled that he was willing to drive one of the Mercer cars, and his services were accepted.

Pullen proved his ability by winning the Grand Prize race at Santa Monica, Cal., Feb. 28, at an average speed of 77.2 miles an hour. Wishart has been seen at the wheel of a Mercer for the past two seasons, and has achieved some signal victories, the most notable of which was his finishing second in the 1913 Indianapolis event in a 300 cubic inch Mercer. Bragg drove a Mercer in the last 500-mile event, but is best known as a pilot of high powered foreign cars. He won the Grand Prize race in 1912 in a Fiat.

AMERICAN CARS POPULAR.

Increase of Sales in Canada Reported by Representative of an American Manufacturer.

American made cars are finding favor with Canadians, according to Fred J. Titus, the former bicycle champion, who returned from a visit to Canada recently. He states that sales are increasing despite the fact that the duty on American machines is 13 per cent. more than on those imported from Europe.

Last year 7212 American cars, representing a value of \$9,233,561, were sold in Canada, as compared with 385 machines valued at \$700,504 disposed of in 1908. Statistics for 1913 indicate an increase of 934 cars over the figures of 1912.

MECHANICAL GEAR SHIFTER.

Vanderveld System Is Actuated by Selector Button on the Steering Wheel.

The Grand Rapids Show Case Company, Grand Rapids, Mich., is manufacturing a mechanical gear shifting device for motor cars, and

it is stated that it is adaptable to used machines as well as to cars in the process of manufacture. It is operated by the clutch pedal and selector buttons on the steering column or wheel. The device is the invention of A. Vanderveld. It weighs about 10 pounds, and is mounted in proximity to the transmission, as will be noted by the accompanying illustration.

The gear shifter proper is mechanical, no springs being utilized. It is connected to the clutch pedal by a lever or arm which has mounted on it two blocks adapted to engage with the gear shifting fingers of the gearset, there being one for each speed, connected directly to rods leading to the push buttons of the selector on the wheel.

Pressing a button raises the finger so selected in the path of travel of the shifting blocks, and the forward movement of the clutch pedal through the blocks contracting with the finger,

Vanderveld Mechanical Gear Shift, Operated by Clutch Pedal and Selector.

pulls the gear into mesh. If a gear be in mesh, and the clutch pedal be pushed forward or depressed, the blocks referred to first contact with a neutralizing member which releases the gear in mesh. Further movement of the clutch pedal places the gear in neutral, and by a still further movement of the pedal blocks contact with that finger selected and the gear is pulled into mesh.

It is pointed out that the pressing of a button does not actually shift a gear, this being accomplished by the forward movement of the clutch pedal. It is also stated that any change of speed may be anticipated by pressing the proper button, and by the next complete forward movement of the clutch pedal the desired speed is obtained. The maker states that the device is positive in action, permits of shifting gears without danger of stripping, etc., and may be attached to used cars.

NOVEL GRAVITY VACUUM FUEL SYSTEM.

FUEL is supplied to the carburetor by two general systems, gravity and pressure. The gravity method requires replacing the main supply at a pre-

Fig. 1—Stewart-Warner Gravity Vacuum Fuel System for Which Many Advantages Are Claimed.

times in a position not easily accessible for adjustment, inspection, etc.

The pressure system generally comprises an air-tight tank, from which the fuel is forced by pressure to the carburetor, a power pump actuated by the energy of the motor, gauge, hand pump, etc. The system is favored by many manufacturers, as it permits placing the carburetor in proximity to the water jackets of the cylinders, the heat of which tends to raise the temperature of the fuel. Another advantage is that a much shorter intake manifold may be employed, which is held to make starting easier in that condensation of the mixture is prevented. With the pressure system, which may be one employing the energy of the exhaust gases, it is essential that all connections be air tight if efficient service is to be obtained.

Factors Eliminated.

The Stewart-Warner Speedometer Corporation, Chicago, has brought out what is termed a gravity vacuum system, which is held to eliminate pumps, air tight tanks, regulators, filters, etc., and to provide a gravity feed of fuel to the carburetor at a uniform pressure at all times and under all conditions of service. One of the qualities of the system is that the body may be suspended in the maximum low position without affecting the steady flow of the fuel. The Stewart-Warner equipment consists of a small tank placed on the dash under the hood or bracketed to base of motor, and a main supply member.

supply at a predetermined or sufficient height above the carburetor to insure a flow of the fuel when the machine is ascending a steep grade. This system frequently necessitates placing the carburetor below the base of the cylinders, and some-

One lead from the Stewart-Warner device connects with the main supply at the rear of the chassis, and it is stated that it is not necessary to employ an air tight construction or to use a leak proof filler cap, as an open vent is employed. One of the features of the system is that the outlet from the gravity tank need be but three inches above the top of the float chamber of the carburetor, which permits locating the carburetor in proximity to the cylinders and in an accessible position.

Two Reservoirs Employed.

Two views of the gravity vacuum system are shown herewith, that at Fig. 1 depicting the device installed on the dash, while that at Fig. 2 is a sectional illustration. By referring to the latter it will be noted that the tank consists of two chambers, a filling and a reserve. The upper compartment is the filling, and the lower has a capacity of about one quart of fuel, this amount being held in reserve at all times.

The filling of the tank is accomplished by tapping the intake manifold at a point nearest the cylinders and utilizing the suction of the intake to draw fuel from the main tank into the smaller vessel. About one twenty-fourth of a gallon is drawn into the small tank at each float operation. It is stated that the pressure utilized does not affect the mixture or modify the operation of the motor.

The fuel drawn into the smaller tank actuates the float and, when the last named member rises to a certain position, it automatically shuts off the supply of air and opens the tank to atmospheric conditions, so that the filling of the upper compartment in no way interferes with the amount of fuel which is supplied to the carburetor.

The operation of the system will be made clear by noting the diagram shown at Fig. 2. C

Fig. 2—Diagram Showing Components of Stewart-Warner Gravity Vacuum Fuel System.

is the line to the intake manifold, and while the drawing does not show it, a small check valve is located in this line just above the valve A, which is the suction valve for opening and closing the connection from the intake manifold and through which the vacuum is forced. D is the line to the main supply.

The atmospheric valve is shown at B and is in an open position. It is stated that it is impossible to have both valves A and B open at the same time, that no particular adjustment of these members is necessary, and that opening the suction valve from .03125 to .25 inch will not affect its operation, hence a fine adjustment is not essential.

Function of Valves.

The operation of the valves A and B is regulated by the float G in the upper chamber, and the float is shown in its top position, just after the compartment has been filled with fuel. The suction valve is closed, and the atmospheric valve, having opened, fuel is flowing from the upper chamber to the lower through the trap valve H. The gasoline in the lower chamber is always under atmospheric pressure, due to the air vent L, which is always open. It is stated that the suction in the top chamber of the tank does not interfere with an even, continual flow of fuel to the carburetor from the lower chamber, because the suction closes the valve H while the upper compartment is being filled.

As gasoline in the upper chamber flows into the lower, and upon the float attaining its maximum low position, the lever E is lowered to such a position that it actuates the valve lever F, and this in turn closes the valve B against atmospheric pressure. The valve A is opened when the suction from the intake manifold begins to draw fuel from the main tank.

Convenient Filter.

The connection to the carburetor is through the line at K. This extends about one inch above the bottom of the lower chamber and prevents water or sediment from reaching the carburetor. Foreign elements thus trapped may be displaced by opening the filter valve J. The latter makes for convenience when a supply of fuel is desired for priming or cleaning purposes.

It is stated that, should the lower tank be empty, only three to five turns of the motor with the throttle closed are necessary to draw enough fuel into the chamber to permit of starting the engine. The only time the suction from the tank shows an effect on the speed of the motor is when the engine is turning over at a very low rate of speed and when idling, and it is stated

that the change is hardly noticeable. Under normal conditions the suction valve is open but approximately two seconds.

Relative to the possibility of fuel being drawn into the intake manifold, it is stated that less than a teaspoonful has been noted in tests and that only when the motor was operating under a load for a period of one hour. It is held that this was due to what little saturation there was in the air, because of its coming in contact with the fuel.

Advantages of System.

Under normal operating conditions the fuel pressure in the carburetor is said to vary but one-quarter of an ounce. Danger of the suction or atmospheric valve sticking is eliminated by the small lever or bar to which these members are attached, it travelling about .25 inch above and striking the valves. The springs attached to the levers are constructed of No. 28 gauge bronze, and have a stretch of .125 inch, making for durability.

The advantages claimed for the Stewart-Warner gravity fuel system are: Ease of installation, steady flow of fuel to the carburetor at an even pressure, elimination of air tight connections, gauges, valves, etc., filtering of the gasoline and locating the carburetor in an accessible position as well as in proximity to the water jackets of the cylinders.

ELECTRIC BICYCLE.

Vaudeville Performer Utilizes Gray & Davis Electric Motor Starter to Propel Machine.

A novel application is noted of an electric motor starter, such as is employed on automobiles, in the application of a Gray & Davis motor to a bicycle. The starter is attached to the bicycle below and directly in front of the usual driving sprocket by clamps. The usual pedal shaft is replaced by a countershaft, this being actuated by silent chain. Final drive to the rear wheel is by the conventional block bicycle chain.

Six-volt storage batteries are utilized to energize the electric motor, the cells being stored in containers on either side of the rear wheel, and mounted on a special frame. Control of the current is by an ordinary knife switch operated by the foot. By wiring the cells in series multiple, the inventor, E. J. Barsden, 446 West 46th street, New York City, claims that he is able to attain a speed of 25 miles an hour for over six hours with the batteries fully charged. The bicycle is utilized by Mr. Barsden on the stage, and he also employs it for pleasure.

MACHINERY, TOOLS, EQUIPMENT AND SUPPLIES.

THE U. S. Electrical Tool Company, Cincinnati, O., is marketing the U. S. electrically operated garage pump shown in the accompanying illustration, and the maker states that it is constructed to withstand severe service. The complete equipment comprises an electric motor, single-cylinder compressor, air tank, suitable length of air hose, lamp cord and socket, gauges, etc., these being mounted on a low truck having caster wheels.

U. S. Electric Air Compressor.

Single castings are largely employed, the pump cylinder, bed and bearing brackets being cast in a single piece. The compressor has a single horizontal cylinder with deep air flanges for cooling, and is driven through a single gear reduction, there being a small pinion on the motor shaft and a very large gear on the pump shaft. Energy is supplied by a .25 horsepower Westinghouse motor, and the current supply is from the lighting system of the building, armored cable of suitable length and a rugged connector being provided.

The crankshaft bearings of the pump are very liberal in size and are retained by bolted-on caps, a method insuring easy removal and adjustment. Lubrication of the compressor is by three oil cups, one on each of the shaft bearings and the third in the cylinder. The method of motor lubrication is such that it will not require attention except after long periods of service.

The crankshaft bearings of the pump are very liberal in size and are retained by bolted-on caps, a method insuring easy removal and adjustment. Lubrication of the compressor is by three oil cups, one on each of the shaft bearings and the third in the cylinder. The method of motor lubrication is such that it will not require attention except after long periods of service.

Air is pumped from the compressor to the tank, which is 12 inches high and six in diameter, and means are provided to trap any oil or moisture that may be present. Nothing but pure fresh air is pumped to the tires. The air hose is unusually long and constructed to meet the requirements of garage service. It is provided with a gauge to indicate the pressure, and the tank is equipped with a similar member of ample size. The usual shut off valve is included.

The maker calls special attention to the efficiency of the outfit, stating that it will inflate a

35 by four-inch tire from flat to 70 pounds in 15 minutes. The truck and wheels are of metal, and the equipment may be moved easily about the garage, a convenient handle being provided for this purpose. The U. S. Electrical Tool Company will supply additional details on request, also trade prices.

MOSSBERG SOCKET BRACE.

The Frank Mossberg Company, Attleboro, Mass., is manufacturing the Mossberg socket brace No. 360, shown in an accompanying illustration. A brace is a decidedly handy tool in the repair shop and garage and may be employed for a number of useful purposes, such as grinding in valves, removing the nuts of demountable rims, working about the power plant, etc.

The Mossberg brace is very efficient, being constructed of the finest grade of steel, dull nickel plated and with ebonized wood handle. It is 13 inches over all and is covered by the usual Mossberg guarantee. The chuck end of this brace holds all sizes of Mossberg sockets and those having a standard shank. The brace is moderately priced.

The company makes a specialty of pressed steel sockets, some of which are shown herewith. The product of the concern is well and favorably known among repairmen and the trade, as the sockets are constructed of pressed steel and hardened, and by their mottled finish. They fit hexagon and square nuts, set screws, and bolt heads. One of their qualities is that they are standard and will fit practically every socket set that is now on the market.

Mossberg Pressed Steel Sockets and Container.

They are produced for U. S. standard hexagonal nuts and bolts, A. L. A. M. standard hexagonal nuts and screws, manufacturers' standard

Mossberg Socket Brace No. 300.

hexagonal headed bolts and for cap and coach screws. The maker calls special attention to the necessity when specifying, that dimensions of nuts should be given measured "across the flats", or, in other words, the smallest diameter of the nut or bolt head, and, unless the actual size of the socket is ordered, an allowance is made by the company of .03125 inch for clearance. The Mossberg sockets are marketed in attractive boxes, each containing one dozen. Prices and complete list of sizes will be mailed upon request.

COWAN TRANSVEYOR.

The Cowan Truck Company, Holyoke, Mass., is manufacturing the Cowan transveyor, shown in an accompanying illustration, which is produced in four sizes, having capacities of 2000, 2500, 3000 and 3500 pounds respectively. One of the qualities of the truck is that it is an all-metal construction. It is designed to operate over rough floors, up and down inclines and with the platforms is held to save considerable time and

The Cowan Transveyor Which Is Utilized with Special Platforms.

labor in the transportation of material about the factory. It is pointed out by the maker that fully 75 per cent. can be saved in the ordinary factory equipment.

One of the features of the transveyor is its ample clearance when the platform is elevated, this being 2.75 inches. The type H transveyor is equipped with a specially designed hydraulic ram, and a few strokes of the handle will elevate maximum loads to a height of three inches, a clearance eliminating possibility of skids catching or encountering obstructions at the foot or top of inclines. It is stated that there is no possibility of the load being released until the operator presses a pedal, when the platform will slowly sink to the floor without shock or jar.

The front wheel of the all-steel construction is fully swivelled, making it possible to turn the machine in its length. The high grade ball bearings are protected by washers and dust caps, and the steering handle is at all times free, enabling the workman to guide the machine easily and accurately. The design of the handle is such that a

Nelson Ford Platen Ring Clamp.

straight pull is provided when removing the transveyor from beneath a platform. The wheels are six inches in diameter for the No. 1 and 2 types and seven for the others. The type H will be supplied with 10-inch wheels if desired. Specifications, dimensions and prices will be forwarded upon request. John Cronin, 118 Pearl street, Boston, is agent for the Cowan Truck Company.

FORD PISTON RING CLAMP.

The Nelson Manufacturing Company, 564 West Randolph street, Chicago, is marketing a number of Ford specialties, among which is a piston ring compressor shown in an accompanying illustration. It is designed especially for the Ford motor and could be employed with other engines the pistons of which are of similar diameter. The operation of the Nelson tool is obvious. It is placed about the ring and by exerting a slight pressure on the handles the ring is fully compressed. The tool is inexpensive and will save considerable time when replacing rings.

ROOTS CARBURETOR USES FORCED INDUCTION.

IT IS stated by an authority on carburetion that when any ordinary type of carburetor is employed, the cylinders of the engine do not at any time receive a full charge of mixture. This is said to be due to the fact that the mixture is drawn into the engine by the partial vacuum caused in each cylinder by the downward movement of the piston on the intake or suction stroke. This defect in the supply of fuel to the engine is held to be more pronounced in some motors than in others, for the timing and the lift of valves have a great deal to do with the matter. For example: If an inlet valve closes too early the amount of mixture drawn in is less than if the valve remained open for a more or less lengthy period after the piston had reached the

Four Views Illustrating Components of Roots Carburetor Utilizing Forced Induction.

bottom of the suction stroke; advantage would not be taken of the momentum of the intruding mixture.

To insure a full charge at all times when the throttle is open is the object of the Roots carburetor, designed by J. D. Roots & Company, London, England. It provides forced induction, a powerful Davidson type of fan being embodied, the duty of which is to draw air past the jets and force the resultant mixture into the cylinders. By this means, mixture under pressure is sent into the cylinders as each inlet valve opens, and the inductive effect of the descending piston or intake stroke is in no way relied upon.

Accompanying sectional drawings show a design in which this principle is embodied. The fan A, which has a large number of very small

blades on its periphery, is intended to be rotated by a pulley or chain ring which would be fitted on the screwed outer end of its spindle. Air is drawn through the bell mouthed inlet B past the jets C, and is forced by the fan blades into the induction pipe outlet D. A rotating sleeve throttle is provided, as shown at E, and this covers or uncovers one or more of the three jets C. These jets are located in separate choke tubes as shown in the bottom right hand view. The throttle is operated by a Bowden wire connection.

It is stated that the carburetor is very efficient, that tests resulted in a car negotiating a grade on the high gear that formerly required use of the second and low with an ordinary carburetor. It is also claimed that with fully open throttle the power of a motor will be increased from 40 to 50 per cent. The effect upon the valves, bearings and other working parts of a motor is not stated.

NOVEL TIME PAYMENT PLAN.

Gerlinger Company Buys Notes from Sub-Agents, Saving Investment of Capital.

The Gerlinger Motor Car Company, Portland, Ore., which has branches in several cities in Washington and Oregon, has developed a plan for time payments which it is maintained will be satisfactory and work out to the benefit of all concerned. This applies to all of the agents for the company who sell trucks on time payments, receiving notes for the balance remaining unpaid. Instead of the agents holding the notes these are purchased by the Gerlinger Motor Car Company, charging for this a nominal sum. Thus the company holds the notes that are made payable to the sub-agents, instead of holding them as direct payments, the benefit being that the sub-agent can deal with those who wish to make time payments and need not himself invest his own capital.

EQUIPPING THE GARAGE.

The purchaser of a new machine who intends to attend personally to its upkeep, will find many valuable suggestions dealing with the selection of the garage equipment in the annual overhaul and equipment number of The Automobile Journal of April 25.

INGENIOUS METHOD OF PLATING METAL.

AN INGENIOUS method of plating almost any surface with metals which are melted fairly easily, such as brass, aluminum, copper, tin and zinc, has been invented by E. U. Schoop, a well known German chemist. The device utilized resembles somewhat a spraying pistol, which is illustrated diagrammatically herewith.

The pistol is provided with a handle, in proximity to which is a supply tap which controls the feed of compressed air and gases used for fusing the plating metal. The gases consist of oxygen and hydrogen, and are supplied by a small tube to the nozzle. Passing through the nozzle is a metal wire, which forms the plating material. Supposing brass is to be used: This wire is about one millimeter (.03937 inch) in thickness, and is gripped between a pair of friction wheels, which are rotated by means of a turbine acted upon by compressed air. Between the turbine and the feed wheels are two worm reductions.

In operation the gases and compressed air are turned on, the former causing a fusing flame to issue from the nozzle, and the air serving, by means of the turbine, to feed the wire to the nozzle. The compressed air also issues in the form of a blast from the nozzle, so that the fused metal, in the form of a spray, is projected with considerable velocity against the surface to be plated, which may be wood, paper, cloth, etc., as well as metal. By varying the feed of compressed air and gas, the speed of operation can be changed and the thickness of the plating deposited can be varied.

About 900 grams of copper or brass can be deposited in an hour, the wire being fed at the rate of about 12 to 15 feet a minute. The process is of interest to motorists, as it suggests a method of plating chassis parts without dismantling or removing them from the car.

TO MANUFACTURE BENZOL.

United States Steel Corporation to Produce Fuel from By-Products of Coke.

The United States Steel Corporation has appropriated \$400,000 for the construction of a plant to manufacture benzol from the by-products of the coke plant of the Carnegie Steel Company at Farrell, Penn. The corporation is said to have had the plan under consideration for some time, and up to the present has been manufacturing coal tar and sulphate of ammonia from

the by-products at the Farrell plant. Benzol is being widely used abroad as a motor fuel, and the production of it in this country will add a new interest to motoring, particularly as benzol can be satisfactorily employed with commercial vehicles.

PROPOSES BOSTON-CHICAGO RUN.

Chicago Automobile Club Agitating Non-Stop Run for July—Approved by Head of A. A. A.

The Chicago Automobile Club is booming the Chicago-Boston day and night non-stop motor reliability run, which it scheduled last summer, but which was postponed because of inability to secure a stock car class. The club aspires to have the Glidden Trophy for the main prize. It is stated that the visit of President Wilson of the American Automobile Association to Chicago recently was responsible for the revival of the plan. It is stated that he tendered to President Vissering of the Chicago club the Wilson cup for the touring car that can show an average speed of a mile a minute over a measured mile course. This same cup was offered at Indianapolis four years ago, but was never won.

The run is tentatively scheduled for July, but details will not be made public until it is known whether or not a stock car rule can be agreed on. It is planned to run off the Wilson trials in September. The conditions require that each car carry four passengers of an average weight of 160 pounds and be fully equipped. There must be two trials, one each way of the course, and the average time will be taken.

BRISCOE COMPANY A MEMBER.

The Briscoe Company of Jackson, Mich., of which Benjamin Briscoe is president, has been admitted to membership in the National Automobile Chamber of Commerce.

Illustrating the Construction of the Schoop Plating Device.

IN THE COMMERCIAL VEHICLE FIELD.

Constructional Details Concerning Hexter Gasoline-Electric Vehicles Announced from New York--Palmer-Moore Company Has Water-Cooled Model.

AFTER experimentation covering some little period, the Roland Gas-Electric Vehicle Corporation was organized in New York City last autumn for the purpose of producing the Hexter gasoline-electric line of trucks, designed by Percy K. Hexter. Quite apart from the fact that these models, of which there are now four, add another make to the list of so-called combination types, the design and construction are such as to merit consideration.

In reality there are two designs, one of which is produced in five and seven tons capacity, and the other, in 1.5 and 3.5 tons. Certain characteristics appear in all sizes, such as the use of a carburetor that is not adjustable, ignition system that eliminates hand control, the governing of the motor to a specific maximum speed, and the elimination of the clutch. It will be understood

stated that the power plant and electric generator installation is the same with all models, except for the dimensions. But one electric motor is utilized in the 1.5 and 3.5-ton machines, this being suspended on a sub-frame that carries the gasoline engine and generator. The driving end of the armature is coupled to the main shaft by a universal joint, and the drive shaft extends to the worm drive mounted in the rear axle housing. This axle is of the full floating type, and the driving thrust is taken through the rear springs, which are shackled at the rear ends only.

The accompanying illustration presents the seven-ton machine, which, with the five-ton model, utilizes two electric motors, these being suspended in the main chassis frame, one forward of and the other behind the jackshaft. The forward motor drives the right side of the jackshaft, and the other the left side, the jackshaft really being two separate shafts that are driven independently of each other. The pinion ends of the armature shafts carry sprockets, which are aligned with larger sprockets on the driving shaft, and these are driven by enclosed silent chain. Drive to the rear wheels is by side chains. There is no differential, the divided jackshaft taking its place, driving thrust being taken by radius rods.

Hexter Seven-Ton Gasoline-Electric Truck, an Interesting New Design Recently Brought Out by New York Concern.

that the gasoline motor is coupled to the electric generator, and this is driven to whatever speed is necessary in order to secure the desired maximum power output from the electric motor.

The generator, in each instance, is a product of the General Electric Company, and is designed to have high efficiency and long endurance. It is compound wound and is arranged to maintain a voltage as nearly uniform as practical, so that increasing the speed of the gasoline motor is held not to add greatly to the voltage, although the amperage is increased and the electric motor is supplied with a greater volume of current. The governing of the gasoline motor is held to insure against excessive speed and protects the electric motor.

With the two smaller sizes the gasoline motors are of the Waukesha make, and it may be

TRACTOR UTILIZES RUNNERS.

Novel Experiment to Overcome Difficulties Attendant Upon Heavy Snowfall.

An accompanying illustration presents a Knox-Martin tractor, made by the Knox Automobile Company, Springfield, Mass., fitted with large runners shod with steel and shaped to be clamped to the free wheels of the combination for affording better traction in heavy snow. The experiment was made, with excellent success, during a recent heavy snow storm in Springfield, and it is stated that the machine was easily controlled and traction was at all times sufficient, no

Knox-Martin Tractor, Fitted with Runners Utilized in Experiment Made by the Knox Automobile Company, Springfield, Mass.

matter what depth of snow it was in. Similar tests have been made with other types of motor vehicles in other cities, and it is not unlikely that something of this nature will be evolved which will prove of service in aiding fire department apparatus, for instance, to overcome the difficulties attendant upon heavy falls of snow.

FAMILY DELIVERY OF COAL.

Some Interesting Results of Year's Experience With Pierce-Arrow Trucks.

Olney & Payne Bros., Pawtucket, R. I., has been operating a fleet of three five-ton, worm driven Pierce-Arrow trucks in the retail delivery of coal for the past year. In fact, one of the machines has been in service about 18 months. The results which have been obtained are such as should prove of interest to others who may be considering the purchase of vehicles for a similar service.

The first machine was purchased to handle contract orders for some of the large factories in the city, and the success which attended its use was such that a second one was ordered shortly thereafter. This was delivered the morning of the second day of a teamsters' strike, and as a result of

this emergency, the third vehicle was ordered for delivery as soon as possible.

Because of the desire to overcome any and all difficulties arising from the labor trouble, the three trucks were set at work handling all kinds of coal orders, including those for family use. The company offered 50 horses and a number of carts for sale, about the same time,

so that there has been abundant opportunity to judge of the possibilities in this field.

It will be understood that the trucks are fitted with specially designed dumping bodies for the quick handling of contract orders. Comparatively few houses are built so as to permit of using these bodies as intended, so that it has been found desirable to add two men to each truck crew to facilitate the work of unloading. Under these conditions it has been found possible, with full loads and efficient operation, to do the work at about the same cost as with horses. The average mileage of the trucks is approximately 50 each day, although as much as 75 miles have been driven to meet some special conditions.

The point which it is desired to make, is that the trucks can be operated with decided economy in the handling of contract work, since this was the factor which determined the purchase of the additional machines in the first instance, and can

Three Five-Ton, Worm Driven Pierce-Arrow Trucks, in Service with Olney & Payne Bros., Coal Dealer, Pawtucket, R. I.

Palmer-Moore Water-Cooled Motor, and Its Location in the Chassis.

be made to handle family orders as cheaply as horses.

PALMER-MOORE'S NEW MOTOR.

Water-Cooled Model Has Been Added for Those Who Prefer This Type.

While the Palmer-Moore Company, Syracuse, N. Y., is well known in the industry because of its production of commercial motor vehicles utilizing a three-cylinder, two-cycle, air-cooled motor, it is of interest to note that this concern has added a new model, which is equipped with an engine of practically the same design, except for the fact that it is water-cooled by the thermo-syphon system. It is explained that this has been developed to meet the demands of those who prefer a water-cooled motor.

The design of the Palmer-Moore engine is somewhat out of the ordinary, it being maintained

by the maker that it is the height of development in the two-cycle field. The cylinders, which have a bore and stroke of four inches, are cast separately, with wide horizontal external flanges or fins about the expansion chamber, and vertical flanges about the head. This construction applies primarily to the air-cooled type. The combustion chamber is spherical. Oil ducts extend from the base of cylinder in the walls to a point just below the top of the piston when at its lowest point. These ducts are never open at the top, but they are held always to be full of gasoline mist, permeated with oil (the same as that consumed as fuel), and that this lubricates the walls of the pistons, the cylinders and the ends of the wristpins, affording positive lubrication and insuring against loss of power. The pistons are constructed with air chambers at the heads, which are held to prevent the heat of combustion overheating the piston heads, rings and wristpins.

A distinctive feature is the valve construction. Instead of the usual form of inlet ports, which are constant with two-cycle engines, the fuel is admitted through ports that are fitted with rotary shutters, connected with linkage and set at any desired position for the immediate requirement. It is maintained that precise control is afforded by varying the opening of these ports, and that the operation of the motor is at all times smooth and even.

When operated in normal conditions and for ordinary work the motor can be best used at from 600 to 700 revolutions a minute, but should

Palmer-Moore 1600-Pound Wagon, Equipped with Latest Type of Water-Cooled, Three-Cylinder, Two-Cycle Motor.

there be occasion the speed can be increased to 1000, which is a reserve for climbing grades, rough roads, sand, or where special power is essential. The statement is made that the ports are productive of a large fuel economy and that there is all the advantage of a low speed engine, minimizing the wear on all bearing surfaces and reducing the probability of overheating. Another factor is the lessened noise of operation. The vibration is also correspondingly reduced.

An accompanying illustration shows the new water-cooled engine, and indicates its location, with the vertical tube radiator incorporated with the dash, and the French type hood, which is lifted from the front to permit of free and full accessibility. The water manifolds are large and the connections are ample for all requirements. Ignition is by Bosch high-tension magneto, with fixed spark, and no other control of the engine is necessary than adjustment of the fuel supply throttle.

Another illustration presents the completed vehicle. The clutch is a three-plate type, with a steel centre plate mounted between two fibre discs. The transmission is a planetary gearset, affording three forward

speeds and reverse, this being assembled as a unit with the jackshaft, with the service brake drums on the outboard ends. The emergency brakes are internal expanding on the rear wheel hubs. Springs are semi-elliptic. The wheels are of the artillery type, carrying 36 by 2.5-inch tires in front and 36 by three-inch in the rear. The capacity of the chassis is rated at 1600 pounds.

CONTRACT STORE DELIVERY.

Equipment Having Private Ownership Appearance Supplied by Cleveland Concern.

The Delivery Company, Cleveland, O., which is now operating a fleet of electric wagons and

several gasoline trucks for general transportation and distribution in that city and suburbs, specializes in two directions. It will make contract to deliver goods of any store on a basis of packages, or it will furnish those who desire to operate personally any type of vehicle with driver at a flat monthly rental.

The company is serving more than 200 different stores, and for a number of firms machines have been provided that have all the appearance of private ownership, being finished with panel bodies bearing the names of the concerns using them, and decorations or lettering that have a distinctive advertising value. Of course, such vehicles are not utilized for any other purposes than those of the firms renting them, and being devoted exclusively to such service they are con-

Type of Baker Electric 1000-Pound Wagon Utilized in Unique Service Furnished by Concern in Cleveland, O.

trolled as though they were owned by them.

When a machine is rented, the price includes the service of the vehicle, the driver, attention, care, maintenance and every detail of operation, the company storing the wagon in its own garage, having all the work done by its mechanics, and systematically maintaining and operating it. The accompanying illustration shows one of the machines, a Baker electric 1000-pound wagon, and indicates the character of equipment provided for those who desire to rent a vehicle in this manner. The plan is meeting with decided success in every respect.

The equipment of the Atlantic Vehicle Company's plant at Newark, N. J., will be sold by referee in bankruptcy. Bids will be opened April 15.

MECHANICAL NOTES FOR OWNERS.

Explaining Flywheel Markings Utilized for Timing the Valves of the Models C, H, N and T Regal Motors--Dish or Camber of Front Wheels.

THE valves are important factors in the operation of an internal combustion engine, and with a four-cylinder, four-cycle motor there are eight of these members, four intake and four exhaust. Their function is to admit the mixture to the cylinders and to permit of the exit of the burned gases. The intake opens when the piston is at approximately the top of its stroke; is closed during the succeeding compression, firing and exhaust stroke. The operation of the exhaust valve is somewhat similar, differing in that it opens when the piston has completed the downward movement and is moving upward. Like the intake it is closed during three strokes or 1.5 revolutions of the flywheel.

It is important that the valves open and close

Valve Timing Diagram of Models C, H, N and T Regal Motors—The Markings Indicate the Correct Opening and Closing Points of the Valves.

according to the factory timing diagram if maximum efficiency is to be obtained from the motor. The factor of mixture is not considered in this discussion. As the valves are actuated by cams, and these are mounted on a shaft driven by the crankshaft, the latter making two revolutions to one of the camshaft, the periphery of the flywheel is utilized to indicate the valve timing.

While at first glance it would appear to the novice that the markings are confusing, they are easily understood if one takes into consideration the operation of a four-cycle motor; that is, the strokes and the number of revolutions of the flywheel.

In an accompanying illustration is shown the

valve timing diagram of models C, H, N and T Regal motors, which is as follows: Intake opens five degrees past centre and closes 40 degrees past centre; exhaust opens 40 degrees past centre and closes seven degrees past centre.

On the rim of the flywheel will be found markings corresponding to those in the illustration, which is drawn to represent the periphery of the flywheel and its marks. It will be noted that there are two lines diametrically opposite each other, the one at the top being 1-4 and the bottom 2-3. These indicate the dead centre positions of the pistons of the first and fourth and second and third cylinders respectively. These marks are essential in valve and ignition timing.

It will be seen that there is an arrow drawn on the cylinder and this is the indicator. When the marks previously referred to register with the arrow, the dead centres are obtained. The arrow is also employed to time the opening and closing points of the intake and exhaust valves.

Assuming that the timing is to be checked: The first step is to open the petcocks to relieve the compression, or the spark plugs may be removed. Next rotate the flywheel to the left until the line 1-4 is opposite the centre line of the cylinders. At this point the exhaust valve of either the No. 1 or No. 4 cylinder should just commence to close. If it is found that the valve of the No. 4 is closing and that of the No. 1 is desired, rotate the flywheel one complete revolution, which will bring the No. 1 valve in position, or so as to register with the arrow. Turn the flywheel about an inch more until the line marked 7 coincides with the arrow. This is the point at which the exhaust valve should just seat or close.

The tappet or pushrod of this valve should not be in contact with the valve stem. If it is, the valve will not entirely close. If there be too much space it will indicate that the valve is opening late and this will be noted easily, as the mark of the flywheel will be past the arrow when the valve begins to seat. The valves are adjustable and by loosening a locking nut and turning the tappet screw up or down the tappet can be so set that the valve will close or open according to the marks on the flywheel.

The inlet valves are checked in the same cylinder by turning the flywheel to the right until

the line 1-4 coincides with the arrow, then turn the flywheel about .75 inch to the left until the line marked 5 registers. At this point the inlet

Sectional View of Model T Ford Motor, Illustrating the Different Strokes of the Pistons and Valves Open and Closed.

valve should just begin to open. The closing point is checked by rotating the flywheel to the left a half a turn, stopping when the line marked 40, just to the right of the line 2-3, registers with the arrow. At this point the inlet should just close.

Any variations from the flywheel markings should be corrected by adjusting the tappets, and if it be borne in mind that each half revolution of the flywheel represents an opening or closing point of a valve, the work will be greatly simplified. A little study of the diagram should enable one to master the valve timing.

OPERATION OF FORD MOTOR.

Many owners of the model T Ford car do not understand the operation of the motor. This subject is discussed in the new manual issued by the Ford Motor Company and the illustrations utilized herein are redrawn from the booklet.

Reference is made to the term cycle, as the Ford motor is a four-cylinder, four-cycle engine having a firing order of 1-2-4-3, which has been employed with all four-cylinder Ford motors. To complete a cycle, or to obtain a power stroke, the piston of a cylinder makes four movements, two up and two down, during which the crankshaft completes two revolutions. These movements of the piston are termed strokes and are as follows: Intake, (piston moves downward); compression, (piston moves upward); firing, (piston moves downward); exhaust, (piston moves upward). It will be seen that but one impulse is obtained during the four strokes which make up the cycle.

The mixture is drawn into the cylinder during the intake stroke, compressed, fired by an electric spark, and the products of combustion are forced out during the exhaust stroke.

An accompanying illustration makes clear these strokes and as the pistons are numbered in sequence, the strokes outlined and valves marked, it should be a simple matter to understand the cycle of operation. In the drawing the No. 1 cylinder (that nearest the radiator) has completed the compression stroke and is about to start downward on the firing stroke. It is approximately at this time that the spark or ignition should occur.

Both valves are closed in the cylinder, as are those in the No. 2, as the latter is about to start the compression stroke. The piston of the No. 3 cylinder is beginning to move upward on the exhaust stroke, consequently the exhaust valve is opening. The No. 4 cylinder is taking in a charge, and it will be seen that the intake valve is off its seat. The intake of the No. 3 and exhaust of the No. 4 are closed. The drawing also shows that when the pistons of the first and

Firing Order 1-2-4-3.

Cylinder 1	Cylinder 2	Cylinder 3	Cylinder 4
1—Firing	Compression	Exhaust	Suction
2—Exhaust	Firing	Suction	Compression
3—Suction	Exhaust	Compression	Firing
4—Compression	Suction	Firing	Exhaust

fourth cylinders are at the top of the stroke, those of the second and third are at the bottom or in a position termed lower dead centre. These points are useful in checking the valve timing and setting the timer.

Another diagram explains the firing order of the cylinders, which is 1-2-4-3. The valves are also lettered. An accompanying table shows the

Showing the Firing Order of the Model T Ford Motor, Also the Valve Arrangement.

strokes taking place when the piston of the No. 1 cylinder is about to descend on the firing stroke.

In the table the operations are uniformly started at the firing point of the No. 1 cylinder. Since cranks 1 and 4, likewise 2 and 3, in four-cylinder engines, have coincident axes, either 2 or 3 may be made the next in firing order after 1. The Ford motor, however, utilizes the second, as previously explained.

An understanding of the firing order and strokes is important, as the data are of value when rewiring the commutator and coil, and when the leads and their terminals have not been marked to insure correct replacement.

DISH OR CAMBER OF FRONT WHEELS.

Some manufacturers dish the front wheels of their cars, among which is the maker of the Buick. It will be noticed that the wheels do not stand straight that they are closer at the bottom than at the top, and that they toe in slightly in front. The amount of divergence from verti-

Dish or Camber and Gather of Front Wheels: A, Showing the Divergence from the Vertical; B, Top View of Wheel, Illustrating Gather.

cal is termed the camber and involves a mechanical principle—that the nearer to an alignment the centre of the spindle bolt and the pivot point of the wheel are when turning, the easier the car will steer.

The proper amount of camber in the Buick models B 24 and B 25 is 2.125 inches. That is, the bottom of the wheels should be that much closer together than at the top. The measurements should be taken between the edges of the rims, and at diametrically opposite points on the circumference. It is an excellent plan in making this measurement, particularly after an accident, to jack up both front wheels and note if they are true. The correction of the camber is a job for the expert or carriage blacksmith.

The gather of the wheels is to offset the effect of the camber, to make the tires wear more

evenly, and also to prevent the wheels wobbling. This is obtained by bringing the extreme forward sections of the wheels closer together by .4375 inch, and the same method is employed as when noting the dish or camber.

The owner can correct the gather by the tie-rod, which is provided with an adjustable yoke. The pin or bolt securing this member to the steering arm is displaced; the lock nut of the yoke loosened, and the yoke rotated to the right to decrease its length or to the left to increase it. Increasing the length of the tierod brings the front of the wheels closer together, augmenting the gather, while shortening it moves the wheels outward. The bolt retaining the yoke should be securely locked, also the nut clamping the yoke.

GARAGE OWNERS ORGANIZE.

Eastern Proprietors Form Protective Association on Lines of Hotel Keepers' Organization.

The Eastern Garage Keepers' Protective Association has been incorporated in New York City by Chester S. Walz of Glenbrook, Conn.; Thomas C. Walz of Pelham, N. Y., and John A. Sanborn of New Rochelle, N. Y., which has been created by the same interests, and will be maintained with practically the same objects, as is now obtained with the Hotel Keepers' Protective Association. The association will sell membership privileges, which will be good for a year, and during that period will supply its members with the names of all persons whose credit is known to be doubtful, this information being furnished by the members and distributed by the organization, which will serve as a clearing house. The cost of membership varies with the proportions of the business.

CONFIDENCE A REQUISITE.

Teacher Says It Is the Main Factor in Developing a Skillful Woman Operator.

According to Miss Frances J. Thornton of Brooklyn, N. Y., one of the few women instructors in automobile driving, the main factor which makes a skillful driver is confidence in oneself and knowledge of the car. She holds that there would be a larger number of women drivers if they would overcome the fear which seems to overtake a beginner, and that the general adoption of the motor starter and lighting system will result in thousands of women operating motor vehicles.

GERMAN CAR STATISTICS.

On Jan. 1, 1913, There Were 57,341 Machines, of Which 49,760 Were Pleasure Cars.

According to statistics supplied the Department of Commerce by one of its European consuls, there were 57,341 motor vehicles in the German empire on Jan. 1, 1913. Of this number 49,760 were pleasure cars and the balance trucks.

The statistics further show that in 1911 there were 113 automobile factories in the German empire, which employed during the year 28,694 persons, with an aggregate salary for the year of \$10,723,566.

The output of machines for 1911 was 11,692 complete cars and 5247 chassis. Of the completed machines 10,319 were passenger vehicles and 1375 freight cars. A further division of the passenger automobiles shows that 4504 were of six horsepower and under, 4269 of six to 10, 1333 from 10 to 25, and only 213 over 25 horsepower.

In 1911 301 trucks were constructed having a carrying capacity of one ton, and 1072 of over that amount. The total value of the 1911 production in the motor car industry was \$38,796,856. The value of the 1912 production was estimated at \$47,600,000.

In 1911 there were 18 factories engaged in the manufacture of tires for motor vehicles, these employing 310 persons. The paid salaries totalled \$2,889,320. The division of tires shows pneumatics manufactured to the value of \$16,860,396, and solid tires to the value of \$4,312,084. Bicycle tires to the value of \$10,987,032 were manufactured. The majority of tires used on German motor vehicles are of German manufacture, although some French makes are becoming popular.

USE OF DENATURED ALCOHOL.

It Is Estimated That Germany Consumes 40,000,000 Gallons Yearly.

According to Charles A. Crampton, commercial agent of the Department of Commerce, Germany uses between 40,000,000 and 50,000,000 gallons of denatured alcohol yearly, of which 30,000,000 gallons are sold to the general public for burning purposes. The importance of this fuel in Germany may be appreciated when it is considered that France uses about 18,000,000 gallons, the United States about 10,000,000, and the United Kingdom only 4,000,000.

According to the monograph issued by Mr. Crampton, copies of which may be procured from

the superintendent of documents, government printing office, Washington, D. C., denatured alcohol is not only gaining in favor for general burning purposes, but a determined effort is being made to find a way to use it as a motor fuel in place of gasoline.

MOTOR CARS IN WAR.

Officers of Both Armies in Mexico Replace Horses with Packard Automobiles.

The automobile is replacing the horse in Mexico, it being utilized by the officers of both armies. A Packard six-cylinder car was purchased recently by Julio Madero, a brother of the late president of Mexico, as a gift to General Obregon, commander of the northern division of Carranza's troops. Madero purchased the machine from a dealer in Phoenix, Ariz., and has practically abandoned the horse.

General Villa also uses a Packard in covering the field. The tonneau of the car has been equipped with special auxiliary seats for members of the staff.

Over 50 Packard vehicles are operated by the federal government in Mexico. They enable army officers to cover a vast amount of ground, and are used also for rapid mobilization of small bodies of troops. The roads in Mexico are held to be very bad.

FIRST CYCLECAR RACES.

Will Be Held at Dr. Percival's Farm, Teaneck, N. J., on Memorial Day.

Dr. Charles G. Percival, who is president of the Cyclecar Club of New Jersey, announces that the first cyclecar competition ever held in this country will be inaugurated on May 30 at the Memorial Day run of the New Jersey Association.

The contests will take place at Teaneck, N. J., and the programme arranged is as follows: Accelerator race of 50 yards; starting cold motors; high average speed event; speed up contest, standing start, one in six; slow race on high gear (miles per hour); fuel economy (pint of gasoline); accelerating contest (standing start); reverse race, 45 yards up grade, and a hill climb.

It is stated that the makers of the Imp, Scripps-Booth, Twombly, Mercury and Economy cars have made entries. The entire association will be the guests of Dr. Percival during the day at his farm at Teaneck, and luncheon will be served previous to the events.

IMPROVED ROADS AND MOTORING LAWS.

Michigan Supreme Court Declares Law Requiring 50 Cents a Horsepower Is Unconstitutional—No Hope for Uniform Statute—Motor Truck Ordinance Dead.

MARCH 26 the supreme court of Michigan handed down an opinion declaring the motoring law passed by the legislature of that state during its session of 1913 is unconstitutional, because "the title of the law was not sufficiently broad to cover the body of the bill" and "it was a license title on a tax law". The decision will prove of interest to motorists in practically every state, as having an important bearing upon the subject of double taxation.

The Michigan law was patterned somewhat after the statute in force in Connecticut, although it went a trifle further than in that commonwealth. The Connecticut law was enacted in 1911, and fixed the license fee for all other motor vehicles than motorcycles, commercial cars, cars operated by hire by liverymen and cars in the hands of manufacturers or dealers, at 50 cents a horsepower. In Michigan the fees for the registration of all motorcycles, motor trucks and automobiles, except those in the hands of manufacturers or dealers, were set at 50 cents a horsepower. The Michigan law expressly stated that these fees should be in lieu of all other forms of taxation, but this does not appear to have been sufficient to save the statute.

According to the secretary of state, approximately \$226,000 had been collected under this law, since it went into effect Jan. 1. This sum must be returned to the automobile owners, with the exception of \$3 for each machine, which was the annual registration fee provided under the old law, passed in 1909.

APPOINTED AS DEPUTIES.

Los Angeles Automobile Dealers to Give Police Department Substantial Aid.

Thirty-two members of the Motor Car Dealers' Association of Los Angeles, Cal., will be appointed special policemen to deal with violations of the speed ordinance, according to present indications. Request for their appointment already has been made to the police department, and is said to have met with the approval of the commissioner. These deputies are to serve without pay and will pledge themselves to take the time to go into court and prosecute a driver

when an arrest has been made.

The plan is said to have originated with Capt. H. D. Ryus of the Oldsmobile Company of Los Angeles, president of the association. He takes the position that reckless driving must cease for the good of the industry, and that existing laws are sufficient for the purpose if properly enforced.

NO UNIFORM LAW.

State Legislatures Refuse to Consider Bill Prepared by Joint Commission.

All hope for a uniform motoring law appears to have been dissipated as the result of the position taken by state legislatures to which the bill prepared by a joint commission, held to represent several of the eastern states, was reported by this commission. In each instance, where this bill has been presented, the legislative committee has declined to consider the bill, on the ground that it did not represent the work of a commission appointed with authority from the states which they purported to represent. Other legislatures will meet next year, so that there is some slight hope that public opinion may be aroused to the point where action will be deemed advisable.

The bill, which was regarded as a desirable working basis, at least, was prepared after much time and thought on the part of the following men: Secretary of State Albert Phillips, Highway Commissioner Charles J. Bennet and Alfred H. Terry of Connecticut; Judge Sylvester Townsend and Charles H. Guyer of Delaware; Attorney-General Scott Wilson, Lyman H. Nelson and J. G. Scates of Maine; Chairman William D. Sohler of the state highway commission of Massachusetts; Highway Commissioner Harry Roe. President H. M. Rowe and Secretary H. M. Luzzius of the Automobile Club of Maryland, representing Maryland; Samuel W. Taylor, Fay C. Parsons and A. J. Deer of New York; Motor Vehicle Commissioner Job H. Lippincott, Highway Commissioner Edwin A. Stevens and George L. Burton of New Jersey; Highway Commissioner E. M. Bigelow and Robert P. Hooper, the latter representing the Pennsylvania Motor Federation of Pennsylvania.

The standing of these men is such as to merit every consideration, but it would appear that this phase of the situation was given little or no thought by those who declined to accept the result of their endeavors to be of service to the public.

TRUCK ORDINANCE DEAD.

Corporation Counsel Informs New York City's Aldermen That Plan Is Illegal.

Some months ago the text of a proposed ordinance taxing motor trucks, introduced in the board of aldermen, New York City, by Alderman McAnney, was printed in full in these columns. It was one of the most drastic measures ever suggested in this country, and its passage would have worked great hardship upon commercial vehicle owners and users, to say nothing of its effect upon the industry itself.

Before taking action on the bill, it was referred to Corporation Counsel Polk, for an opinion as to its legality. That opinion has been filed, and sets forth in effect that, while the board undoubtedly has the power to regulate the use of city streets, it has no power to fix a direct tax for revenue purposes. He adds that he feels compelled to advise the board that it cannot legally enact the ordinance as drawn.

Motor truck owners and users, particularly members of the Motor Truck Club, feel convinced that no further attempt will be made to regulate the weight of vehicles in the manner suggested.

MANY MOTOR CAR BILLS.

More Than 160 Relating to Vehicles and Highways Introduced in Legislatures.

In the first 10 weeks following the opening of the legislatures in January, more than 160 bills relating to or directly affecting motor vehicles and highways were introduced. The bills were diversified, some creating highway commissions, requiring lights at night on all vehicles, authorizing the placing of warning signs at dangerous turns and hills, etc. Others are not viewed with favor by owners and the industry as a whole.

In the last named class is mentioned a New Jersey bill which would compel shading or hooding the headlights so that the rays would not be cast at a greater elevation than five feet from the ground. Rhode Island has a bill in contemplation which specifically forbids the operation of any vehicle "to which there are lights attached

of such candlepower as will throw rays 200 feet ahead".

The obvious purpose of a large proportion of the bills is to produce funds which can be applied to road maintenance and construction. By putting a proportionate tax on horse drawn vehicles, it is estimated that the yearly vehicle license fund for road work would be doubled.

WILL TEST VALIDITY OF LAW.

Wisconsin Motorists to Fight Registration and Owners' Fee, Claiming Double Taxation.

The motor clubs of Wisconsin have combined to test the validity of the law requiring the registration of motor cars and the payment of a \$5 fee by private owners at the beginning of each year. This is the result of the recent successful action against annual registration fees in Ohio. Milwaukee motorists claim that they are subjected to double taxation, as the state collects a license fee and also a personal property tax on automobiles. As the personal property tax is higher than the annual license fee in a great majority of cases, it is suggested in some quarters to compromise the situation by making the license fee receipt an offset on the personal property tax payment. In the payment of the income tax in Wisconsin the personal property tax receipt is an offset.

The motor registry fees in Wisconsin are as follows: Private owners, \$5; dealers, \$10; motorcyclists, \$2; transfer of license from one car to another during one year, 50 cents. The net proceeds now go into the state highway fund.

MUST PAY BACK FEE.

Secretary of State in Iowa Holds That Purchaser of Second Hand Car Is Responsible.

According to a report from Des Moines, Ia., the secretary of state has made a ruling that a person buying a second hand car must see to it that the registration fee for the previous year has been paid. It was also ruled that the Iowa registration fee for motor cars is a police measure, not taxation.

The decision was made in the case of a man who purchased a 1913 car recently, and for which the previous owner had not paid the 1913 fee. It is stated that the case will be threshed out in court. The reason advanced by the secretary for the ruling is that the fee is the same for a \$600 or a \$7000 car.

THE FARR TRANSMISSION GEARSET.

A PATENT has been granted to Herman G. Farr, a mechanical engineer of Springfield, Mass., who has assigned this to the Knox Automobile Company, which covers the construction of a motor vehicle power transmission gearset, designed for use with machines built for freight service. The gearset is a conventional type with sliding gears that may be selected at will so as to afford any desired speed ratio, but as designed it is intended for incorporation with a differential casing such as is constructed for the jackshaft of the chain driven machine, and assumedly is not combined with rear axles of the floating construction.

Components of Gearset.

The gearset and differential casing are divided longitudinally, the lower section carrying the gearset and the differential gearing, the upper

The Farr Transmission and Gearset: At Left, Plan View, Showing Combination with Differential; at Right, Top, Longitudinal Section at the Figures 2-2; Bottom, Transverse Section at the Figures 3-3.

portion being practically a cover. The gearset itself is built with the main shaft and the countershaft paralleling at the same height, with the reverse stud shaft carried below, the main shaft carrying the movable gears, which are coupled by dog clutches. The gearset does not differ in the constructional details from the conventional type up to this point, but instead of the bearings carrying the shafts being mounted in the end walls of the casing the case carries a frame in which the entire gearset, including the pinion shaft, is mounted. This frame or cage is in two parts and is bolted together at a point near the centre, the frame members being substantial in construction and designed to endure under heavy stresses.

The ends or head members of the frame are

fitted accurately into the casing, so that the gearset as an assembly is rigidly supported, and these are retained in the case by substantial studs that are inserted externally through the case. When assembled the frame is practically a part of the case, but by the removal of the cover of the case and the retaining bolts the frame with the shafts, bearings, gears and pinions may be removed from the casing. The value of the construction is that with comparatively little labor the gearset may be taken from the case for examination, and it may be placed on a bench practically operable, when it can be tested, and if repair is necessary it can be assembled and tried before being placed in the casing.

Saves Time and Labor.

The removal of the gearset as an assembly is known to be a decided saving in labor, as well as an insurance that it is operative, while all parts can be worked on with much greater ease and rapidity while on a bench than in the vehicle. The clearing of the case of the gearset also makes practical and easier the work that may be necessary with the differential, so that this need not be removed save for repair, as adjustment can be easily made, and the casing can be completely cleaned without much labor and with assurance that the gearset will be in perfect condition when restored to the case. The removal of the cover section of the case affords the same access that is had with the ordinary construction, and should there be need the gearset may be taken out with comparative ease.

In the drawings reproduced, a is the gearset and differential case, b the differential, c the extension of the rear head to support the main shaft bearing, d the bevel gear of the jackshaft, e and f the head members of the gearset frame, g and h the supporting members for the gear shifting rods, i and j the gear shifting rods, k the main shaft, l the countershaft, m the reverse stud shaft, n and o the gear clutches, n' the frame or cage connection flanges, and r the frame or cage. The accompanying illustration of the gearset is very comprehensive, as it gives the detail of construction clearly. The top or plan view is of the gearset assembled in the case and as a unit with the differential gearing, for the removal of the cover exposes every part of the assembly, and the end or frame members that contain the gearset can be noted as supplying the conventional solid ends of the casing.

Aside from this sectional design the case conforms to ordinary construction. Turning to the

upper right sketch in the illustration it will be noted that this is a vertical longitudinal section, at the points designated at 2—2 in the plan view, and this indicates the end members and the stud bolts retaining them, as well as the flanges of the frame, which are bolted together directly over and under the gear, the flanges forming a web that materially stiffens the frame when assembled.

It will be seen that the end members are heavily constructed and intended to endure hard service. The lower right sketch is a transverse section at the flanges of the frame, at the point indicated in the plan view as 3—3, this indicating the relative positions of the shafts and gears.

MOTZ TIRES PROMINENT.

Were Largely in Evidence on Electrics at Motor Car Shows.

According to figures compiled by the Motz Tire & Rubber Company, Akron, O., maker of the Motz cushion tire, its product was largely in evidence at the shows. With the close of the Boston exhibit it was figured that at the six leading shows 70 of the 134 electric cars exhibited were equipped with the Motz tire.

TO PLACE SIGNBOARDS.

Wyoming Automobile Association to Mark Roads Throughout That State.

A movement is on foot to mark the automobile roads throughout Wyoming by the Sheridan Motor Club. Dr. Stahl, a member, while visiting Colorado, was greatly impressed with the signboards put up in that state by the Denver Motor Club, and intends to call upon the county commissioners and the Wyoming State Highway Association for assistance in the matter.

WILL MANAGE ELGIN RACES.

Chicago Automobile Club Signs Agreement to Promote the Annual Road Race.

An agreement has been signed between the Chicago Automobile Club and the Elgin Automobile Road Race Association whereby the former will again promote the annual Elgin road race. The dates have been changed from those assigned by the contest board of American Automobile Association: Instead of being Aug. 28-29, they will be Aug. 21-22, the change being made to avoid a conflict with the Pomona speed-

way race, which has been assigned to Sept. 9.

The Elgin programme has been altered, the small car event having been abandoned and the Chicago Automobile Club trophy event will be for cars of 450 cubic inches and under, instead of 300 and under. The Elgin National trophy race will be a free-for-all instead of for cars of 400 cubic inches and under.

W. O. RUTHERFORD PROMOTED.

Is Elected Assistant General Sales Manager of the B. F. Goodrich Company.

W. O. Rutherford, well known in the tire industry, has been made assistant general sales manager of the B. F. Goodrich Company in recognition of his ability in meeting and handling critical situations in the selling field. The change carries with it official recognition of the duties which have been performed by Mr. Rutherford during the past four years as assistant to H. E. Raymond, second vice president and general sales manager. Mr. Rutherford has displayed ability in organization of sales forces and the announcement of his promotion will be noted with pleasure by his hosts of friends in the automobile industry.

W. O. Rutherford, Assistant General Sales Manager of the B. F. Goodrich Company.

He first demonstrated his qualifications as a sales manager at the Denver branch of the B. F. Goodrich Company, and was for 10 years at the head of the Buffalo, N. Y., organization. During the past four years he has made his headquarters at Akron, O. Mr. Rutherford takes his promotion modestly and attributes it to a close application to the many details of the industry.

NEWS OF THE MANUFACTURER AND DEALER.

The following concerns have been incorporated recently to manufacture and deal in motor cars, accessories, etc.:

Girton Hoffer Company, Los Angeles, Cal.; to deal in motorcycles.

Electric Auto Association, Youngstown, O.; \$24,000.

G. & Z. Garage Company, New York City; \$20,000; to operate a garage; S. S. Zula, B. Gorschalki, L. E. Swartz.

Fiat Motor Company, Chicago, Ill.; \$2000.

Broad Street Garage & Sales Company, Palmyra, N. J.; to deal in automobile supplies.

George W. Canterbury Company, Boston, Mass.; \$50,000; to deal in motor cars; George W. Canterbury, Henry G. Lapham, Samuel D. Pope.

Ashland Motor Livery, Chicago, Ill.; to deal in automobiles.

Burgh Taxi Cab & Garage Company, Chicago, Ill.; \$1000; to operate a garage.

Atlantic States Sales Company, Philadelphia, Penn.; \$25,000; to manufacture and sell automobiles and accessories.

Laredo Auto Sales Company, Laredo, Tex.; \$12,500; J. R. Moore, W. J. Sames, J. E. Applewhite.

South Butte Auto Company, Butte, Mont.; to conduct an automobile and accessory house.

Middle States Motor Company, New York City; \$5000; A. C. Beck, C. F. Marion, D. D. Kaess.

Bacon-Wain Motor Sales Company, Toledo, O.; to conduct a general automobile business.

Ocean Shore Auto Storage Company, San Francisco, Cal.; \$25,000.

Atlas Tire Association, Augusta, Me.; \$10,000; E. M. Leavitt, E. L. McLean.

Wilson's Ford Specialty Corporation, Buffalo, N. Y.; \$12,000; to deal in automobile accessories; K. R. Wilson, C. F. Schultze, A. C. McCall.

Respiro Motor Company, Memphis, Tenn.; \$25,000; to deal in automobiles; C. M. Hammonds, W. G. Cavett, T. E. Acklen, T. Irvin, R. Troutt.

Wisconsin Oil & Supply Company, Milwaukee, Wis.; \$7500; to deal in lubricants, fuels, etc.; H. H. Gerlach, P. J. Klumb, C. Weckmueller.

Eagle Chemical Company, Milwaukee, Wis.; \$25,000; to manufacture and deal in chemicals; E. D. Fowle, W. E. Jones, R. E. Winibigler.

Mason Bros., New York City; \$10,000; E. J. Ellenwood, S. H. Mason, C. S. Mason.

Washington Heights Taxicab Company, New York City; \$1000; R. E. Topping, M. L. Topping, G. Kirwin.

Wood Motors Company, New York City; \$2000; J. E. Wood, Jr., F. McKenna, H. R. Partridge.

American Road Appliance Company, Ocean City, N. J.; \$500,000; to manufacture motor car road sweeping machines; H. Pezzetti, B. T. Moore, D. de Benedictis.

Ahlberg Kerosene Carburetor Company, Pittsburg, Penn.; \$300,000; Harry Davis, P. W. Burke, N. J. Dain.

Beechwood Garage, Rochester, N. Y.; to conduct a garage; E. E. Russell, W. Hiller.

Pacific Cyclecar Company, Seattle, Wash.; \$40,000; F. W. Bishop, T. F. Murphine, T. Anderson.

A. L. Robertson Motor Supply Company, New York City; \$32,000; to conduct a motor car business; G. E. Smith, A. Keogh, W. W. Hoffman.

Whitfield Starter Corporation, \$12,000; to manufacture starters; T. M. Day, G. E. Foley, L. F. Mentz.

The End-Oxy Appliance Company, Trenton, N. J.; \$50,000; Earl H. Endebruck, Frederick H. Endebruck, Robert J. Erlichman.

New Orleans Cyclecar Company, New Orleans, La.; \$17,500; to manufacture motor driven vehicles; Julius C. Werner, Isaac T. Rhea, William S. Campbell.

David Acetylene Gas Generator Company, New York City; \$10,000; Louis Strinban, Dave Strinban, Henry Melzer.

The Whyer's Automobile Company, Stockton, Cal.; \$10,000; to conduct a general automobile business; F. B. Alida, Raymond F. Whyers, L. D. Myers.

Eagle Auto Transfer Company, Chicago, Ill.; \$15,000; garage transfer and delivery business; Samuel A. Miller, Elizabeth Gradley.

American Electric Car Company, Portland, Me.; \$1,500,000; to manufacture and deal in automobiles and parts; F. A. Brand, T. Huss and others.

The Consumer's Auto Supply Company, Youngstown, O.; \$10,000; to conduct a garage and automobile business; Charles B. Jackson, Max M. Reese, Clate L. Baldwin, A. V. Hinman, R. E. Robinson.

Kokomo Welding Company, Kokomo, Ind.; \$1000; J. M. Klein, Rude Brown, W. A. Ulrich.

Singer Motor Company, New York City; \$200,000; to manufacture automobiles; Charles A. Singer, Sr., Charles A. Singer, Jr., Harold Callisen.

Central Screw Company, Chicago, Ill.; \$25,000; to manufacture and deal in valves; H. F. Kellogg, O. M. Dennis, F. M. Kingsley.

Irwin Automatic Signal Company, St. Louis, Mo.; \$50,000; to manufacture automatic signals; Charles F. Smith, John J. Dillon, William G. Berg.

Waterbury Tire Company, Waterbury, Conn.; \$2500; George J. Richards, James Powers, Frank Hayes.

City Auto Repair Company, Hartford, Conn.; to operate a garage.

Giant Tire & Rubber Company, Lincoln, Neb.; \$20,000; to engage in the automobile tire business; J. E. Fitzgerald, J. C. Root, R. W. Parker, John T. Yates, R. W. Morrison.

Distillate Motor Equipment Company, San Francisco, Cal.; \$100,000; to deal in motor parts; H. M. McDonald, W. W. McDonald, G. S. Bartlett, A. R. Larn, W. Barnes.

GARAGE AND DEALER.

Horn & Willis, Ennis, Tex., has purchased the Interstate Garage and will operate it under the name of the Ford Garage.

Wilmarlin Wallace, Blairstown, N. J., will open a new modern garage.

J. Van Benschoten, Poughkeepsie, N. Y., is having extensive improvements made to his garage.

Miller & Dietrich Auto Exchange Company, Point Marion, Penn., is to erect a large and modern garage and machine shop. Up-to-date machinery will be installed.

The Capital Garage & Engineering Company, Carson, Nev., has opened a garage and repair shop. It is modern throughout.

Louis M. Stever, Richmond Hill, N. Y., has been appointed general representative in the United States for the Gas-O-Meter Maximall, which is manufactured in Germany.

The Stanley & Fenton Company, Clinton, Ia., has opened its new and modern garage. The company handles the Auburn cars.

Matrud & Thompson, Hatton, N. D., has opened a tire vulcanizing plant in the Stevens building. The company also conducts a general repair business.

The Motor Inn Company, Albert Lea, Minn., has purchased a lot with 26 feet frontage on Broadway upon which an addition will be made to its large building.

J. P. Marks, Le Sueur, Minn., has purchased W. H. Rethwill's garage.

The Slayton Auto Company, Slayton, Minn., is making extensive improvements to its garage.

The Shafer-Decker Company, Rochester, N. Y., has been forced to move to larger quarters at 15 Circle street. The garage is open day and night.

Knass & Schermerhorn, Grand Rapids, Mich., has purchased the Wealthy Heights Garage. Edward J. Strong, the former owner, has retired from the business.

C. A. Kroehne, Springfield, Mass., has purchased a garage at 57 Pecowsic avenue, where he will handle Gray & Davis products. He will also specialize in the repair of this equipment and the Bosch magneto.

W. P. Gribble, Houston, Tex., has disposed of his interest in the Houston Motor Car Exchange. He will handle the Partin-Palmer cars and has opened a salesroom for that purpose.

Smith & Morrison, El Centro, Cal., has purchased the Central Garage.

The Borough Garage, Plainfield, N. J., has been purchased by H. J. Scandell and C. M. Haight. G. M. Romond will be the manager.

Henry H. Hyder, Riverside, Cal., is to open a new and modern garage at 446 West Eighth street. He will secure a car agency in the near future.

Brink & Payne is a new firm at Grand Rapids, Mich., which will engage in the automobile trimming business. The company will be located at 14 Island street.

The Haynes Automobile Company, Kokomo, Ind., has arranged with H. T. Sheffield, Calgary, Alb., to handle the company's cars in that territory. Mr. Sheffield is a well known automobile dealer.

D. C. Cain, Columbus, O., who is the agent for Ford cars, has added an electric charging plant to his taxi and repair service.

The Fisk Rubber Company, Los Angeles, Cal., is now located in its new home at 10th and Hope streets.

Edgar Updyke, Indianapolis, Ind., has moved to more commodious quarters at 343 North Capitol avenue. He is agent for the American car.

Martin Swintek, Eddyville, Ia., is erecting an up-to-date garage on North First street. A general storage and repair business is to be conducted.

Louis Peterson, Hartley, Ia., has purchased the Startling-Steece garage, and will combine with A. F. Palmquist, who is agent for Ford cars, in making it one of the largest establishments of this nature in the city.

The Litchfield Auto Company, Litchfield, Minn., has installed an electric drill in its large garage.

Virgil Collins, Ashley, N. D., is building a garage, where he will conduct a repair shop and storage business.

The Rochester Tire & Repair Company, Rochester, Minn., has opened a new vulcanizing plant at 18-20 East

ment being especially packed for the long journey.

The Maryland Electric Vehicle Manufacturing Company, Baltimore, Md., has been incorporated to manufacture the Maryland electric commercial car. The company has opened its factory and will make a feature of 1000-pound vehicles to sell for \$1250. The company will also make cars up to 10,000 pounds. William Knoblock is manager.

The Hartford Auto Parts Company, Hartford, Conn., has contracted to supply the American Cyclecar Company, Bridgeport, Conn., with \$200,000 worth of parts for its cyclecar. Transmissions will constitute the main part of the order.

The Northern Engineering Works, Detroit, has undertaken the manufacture and sale of the Thurber rotary starter, and the business of the Thurber Rotary Starter Company will be handled by it through its Thurber rotary starter department.

The Universal Tire Company, Los Angeles, Cal., has purchased the Dryfus Winery at Anaheim, Cal., for the purpose of establishing an automobile tire factory.

The Mansfield Tire & Rubber Company, Mansfield, O., has completed its three-story addition and it will soon be ready for occupancy.

The Briggs Manufacturing Company, Detroit, which manufactures automobile bodies, has acquired the large plant formerly occupied by the A. C. Knapp Trimming Company. It is three stories high and is 200 by 210 feet.

The Crown Motor Company, New Albany, Ind., has

A Corner in the Shipping Department of the No. 3 Studebaker Plant, Detroit, Showing Crew of Men Boxing the Automobiles for Export.

Fifth street. E. J. & A. J. Kos is to manage the affairs of the company and will stock Federal and Pennsylvania tires.

The George W. Bolton Company, Detroit, has purchased the business of the Colonial Tire Repair Company of that city.

C. A. Chambers, Indianapolis, has taken over the business of the Krit Motor Car Company. He is also agent for the Federal trucks and is located at 334 North Delaware street.

Yawkey & Mats, South Bend, Ind., has opened an automobile accessory store.

S. A. Woldrick, Sleepy Eye, Minn., has purchased three lots on Main and Fourth streets on which he intends to erect a garage.

WITH THE MANUFACTURERS.

The Studebaker Corporation, Detroit, during the month of February exported daily more than 40 Studebaker cars to its distributors in Great Britain, Europe, Australia, Singapore, South Africa and the Far East. An accompanying illustration shows a corner of shipping department in No. 3 plant of the Studebaker Corporation, Detroit. To facilitate handling, each car is placed in a crate, its wheels, top, windshield and general equip-

ment being especially packed for the long journey. purchased from Ferdinand Kahler the automobile factory on Vincennes street formerly occupied by the Ohio Falls Motor Car Company. The price paid was \$50,000. A representative of the company states that the concern will employ 600 men and that 10,000 machines will be manufactured between now and Sept. 1.

The Amplex Manufacturing Company, Mishawaka, Ind., will produce a medium priced six-cylinder car designed by E. J. Gulick, who was the former engineer of the Simplex Company. The designing and general management will be in charge of Mr. Gulick, while the management of the plant will be in the hands of Mr. Randall.

The Springfield Spring Company, Springfield, O., has taken over the former plant of the Owen Machine Company. The building will be remodelled into a plant for the manufacture of all kinds of springs. The company has increased its capital from \$35,000 to \$60,000.

The Canadian Products, Ltd., Guelph, Ont., has purchased the plant of the Standard Fitting & Valve Company. The president of the new company is W. B. Hinman. The concern will manufacture high carbon steel structural tubing.

The Walker Starter Company, Laporte, Ind., has purchased the property in which it has been operating, which includes two lots and buildings on Monroe street. The company manufactures starters for automobiles, traction engines and stationary engines.

CRITICISM OF SAFETY FENDERS.

AN INJURY or fatality resultant from a motor vehicle striking a person in its path immediately causes the assumption by a very large proportion of the public that protection should be afforded by equipment carried by machines. The thought is perhaps logical, but how this condition can be met is a subject that has received a great deal of attention by those who have the welfare of the public, the motor vehicle industry, and the owners of the machines to consider.

The first municipality to enact an ordinance requiring fender equipment was Detroit, which has recently repealed this measure, and this was followed by a similar ordinance enacted in Chicago. Later on an ordinance offered in the Cleveland, O., city council was not favorably reported by the committee to which it was referred, and the Milwaukee, Wis., city council rejected an ordinance having practically the same purpose.

The experience with the ordinances of Detroit and Chicago has been followed very carefully by the industry and its various organizations, as well as the industrial and trade press, with a view of ascertaining the results from the practical utilization of such fenders as have been developed. Broadly, it may be stated that no satisfactory fender has yet been conceived.

The possibilities from agitation of fender equipment has impelled the National Automobile Chamber of Commerce to learn from service vehicle manufacturers and users in Detroit and Chicago the effects of the ordinances, and the opinions as to the practicability of fenders as applied to machines in those cities. No one of more than 20 responses to inquiries has been favorable to the use of fenders, and practically all point out the inefficiency of those that have been tried, as well as the possibility of increase of accidents through their use.

In Detroit the ordinance became effective Oct. 1, but upon representations made by motor car owners the time was extended to Nov. 1 by the police commissioner, because he could not approve any fender submitted, and later was extended to Jan. 1 by the same official. After that time endeavor was made to enforce it, but it caused such hardship for motor vehicle owners because of the impossibility of obtaining a satisfactory fender, that in March the ordinance was repealed. The experience of the police commissioner was that there was no apparent diminution of accidents because of the use of fenders.

Those who have observed conditions and studied the subject of fenders are very generally united in criticism, which may be summarized as follows:

That such fenders as are now available are as likely to cause injury or fatality as to prevent, that they increase traffic confusion, that they are easily damaged and made inoperative, that no satisfactory or effective type of fender is known.

In connection with this an analysis of the records of street accidents in Cook county, made by the coroner of Chicago, is of interest, from the fact that it was established that motor vehicles have caused about half the number of deaths resultant from horse vehicle accidents when the miles travelled is taken as a basis.

The Pierce-Arrow Motor Car Company has published a pamphlet dealing with the subject, in which are summarized arguments for and against the use of fenders, prepared by its engineering department, and this is being distributed to those who are desirous of learning the facts, in which it is stated that a fender that would save life, provided it was made in a manner and of material that would endure, could be easily applied and kept in good repair, would be welcomed by all. Such a fender would be adopted, but legislation compelling the adoption of any unproven device that might be offered for the purpose is deprecated. The report of the public service commission for the first district of New York State, which was published Dec. 29, 1908, on car fenders and wheel guard tests, is referred to. This report can be purchased at 150 Nassau street, New York City. The report deals with tests made with life size dummies, very carefully made to represent actual conditions, with the comment that these trials were with street cars over a fairly good bed in a fixed direction. The comment is made that the gist of this report is that very careful and elaborate tests should be made before deciding on a fender, and that many fenders which would seem to be valuable were more dangerous than if not used.

EQUIPPING THE GARAGE.

The purchaser of a new machine who intends to attend personally to its upkeep, will find many valuable suggestions dealing with the selection of the garage equipment in the annual overhaul and equipment number of The Automobile Journal of April 25.

RECENT PATENTS.

Mounting for Headlights, William E. Nickerson, Cambridge, Mass., assignor to Everett D. Chadwick, trustee, Winchester, Mass.; No. 1,089,430. Filed June 16, 1911.

Motor, Olof Ohlsson Sodartelje, Sweden; No. 1,089,432. Filed May 22, 1907.

Wheel, Birt B. Stepleton, Downing, Mo., assignor of one-half to E. J. Goines, Memphis, Mo.; No. 1,089,445. Filed Nov. 25, 1912.

Jump Spark Ignition Apparatus, Mark B. Crist, Pittsburg, Penn., assignor, by mesne assignments, to Capitol Trust Company, trustee, same city; No. 1,089,461. Filed Feb. 15, 1906.

Motor, Mark B. Crist, Pittsburg, Penn., assignor by mesne assignments, to Capitol Trust Company, trustee, same city; No. 1,089,462. Filed April 20, 1910.

Rotary Engine, Lafayette Holt, Burlington, N. C.; No. 1,089,469. Filed May 28, 1912.

Carburetor, Howard B. Hunt and William S. Peloubet, Los Angeles, Cal., assignors to Hunt Gas Machine Company, Minneapolis, Minn.; No. 1,089,471. Filed Feb. 14, 1913.

Motor, Alexander T. Kasley, Swissvale, Penn., assignor, by mesne assignments, to Capitol Trust Company, trustee, Pittsburg, Penn.; No. 1,089,478. Filed Sept. 1, 1909.

Sectional Resilient Tire, Charles A. Marlen, St. Louis, Mo.; No. 1,089,489. Filed March 9, 1912.

Carburetor, John Ruthven, Indianapolis, Ind.; No. 1,089,501. Filed Aug. 30, 1912.

Wheel, Alfred J. Swing, Cincinnati, O.; No. 1,089,511. Filed Feb. 26, 1913.

Carburetor, Walter C. Westaway, Belvidere, Ill., assignor to William W. Lufkin, Beloit, Ill.; No. 1,089,516. Filed June 12, 1911.

Carburetor, Herbert Raymond Barrett, Southport, and Kenneth McClymont Wilson, Manchester, England, assignors to Phoenix Motor Company, Altrincham, England; No. 1,089,524. Filed Nov. 6, 1911.

Valve Gearing, Harry W. Bolens, Port Washington, Wis.; No. 1,089,526. Filed June 28, 1912.

Storage Battery System, Edward A. Halbleib, Rochester, N. Y., assignor to North East Electric Company, same city; No. 1,089,549. Filed Jan. 16, 1913.

Automobile Lock, Herman J. Neumann, Los Angeles, Cal.; No. 1,089,581. Filed Oct. 5, 1912.

Pneumatic Suspension Device, John Williamson, Brooklyn, N. Y., assignor of one-third to Harvey E. Randall, and one-third to Albert P. Stewart, same city; No. 1,089,610. Filed Dec. 28, 1911.

Valve, Harry E. Bailey and Clyde Parsons, Green Castle, Mo.; No. 1,089,620. Filed March 24, 1913.

Wheel Rim, Richard F. Gelde, Rochester, N. Y.; No. 1,089,624. Filed Nov. 21, 1913.

Motorcycle Steering Mechanism, David James Johnston, Toronto, Ont., assignor to Militaire Auto Company, Inc., Cleveland, O.; No. 1,089,647. Filed Jan. 29, 1913.

Ratchet Wrench, Gordon K. Wright, Hinsdale, Ill., assignor to Chicago Manufacturing & Distributing Company; No. 1,089,737. Filed March 19, 1913.

Reflecting Lamp, Harry A. Douglas, Chicago, Ill.; No. 1,089,750. Filed Aug. 5, 1912.

Motor, James M. Morgan, Royal, Ia.; No. 1,089,779. Filed May 4, 1912.

Mixer for Gaseous Fuel, Herman E. Whiting, Palmyra, N. Y., assignor to Garlock Auto Specialty Company, same city; No. 1,089,804. Filed Feb. 15, 1911.

Piston, Charles Day and George E. Windeler, Stockport, England, assignors to General Electric Company; No. 1,089,823. Filed June 13, 1912.

Shock Absorber, Wiley R. Frommater, Long Island City, N. Y.; No. 1,089,830. Filed Nov. 14, 1913.

Ball Bearing Retainer, Gustav H. Stahl, Chicago, Ill.; No. 1,089,877. Filed April 24, 1913.

Gas Turbine, Heinrich Zoelly, Zurich, Switzerland; No. 1,089,892. Filed Jan. 6, 1913.

Sectional Cushion Tire, James H. Bedell and Isaac E. Bedell, Stamford, Conn.; No. 1,089,897. Filed Sept. 19, 1912.

Pneumatic Tire, Jerome J. Dittenhoefer, Chicago, Ill.; No. 1,089,913. Filed Sept. 2, 1913.

Motor Starter, Henry S. Rauch, Jackson, Mich.; No. 1,089,962. Filed Feb. 2, 1912.

Pneumatic Support and Shock Absorber, S. Walter Scott, Troy, N. Y.; No. 1,089,974. Filed July 17, 1912.

Spring Wheel, Frederick Stitzel, Louisville, Ky.; No. 1,089,979. Filed Jan. 15, 1913.

Valve Mechanism, Ural Stiwell Traub, Yonkers, N. Y.; No. 1,089,989. Filed March 13, 1912.

Air Supply Means for Motor, William A. Watkins, Riverside, Cal., assignor of one-half to Sidney A. Ratliff, same city; No. 1,089,998. Filed June 20, 1913.

Radiator, Adelard J. Carriere, Putnam, Conn.; No. 1,090,023. Filed Feb. 1, 1913.

Self-Propelled Power Machine, Arthur S. Clemons, Bartlett, N. H.; No. 1,090,027. Filed Oct. 26, 1912.

Carburetor, Maurice Goudard and Marcel Mennesson, Levallois-Perret, France; No. 1,090,047. Filed Nov. 26, 1912.

Resilient Wheel, George Hunter Robinson, Bayswater, London, England; No. 1,090,087. Filed June 16, 1913.

Motor Starter, Frederick Richard Simms, London, England; No. 1,090,109. Filed July 14, 1913.

Rim, Benajah Bradford, Norristown, Penn., assignor to Lee Tire & Rubber Company, Conshohocken, Penn.; No. 1,090,114. Filed March 29, 1910.

COMING EVENTS.

April.

April 9-15—Show, Manchester, N. H.

April 12—Show, Palermo, Italy.

April 12-19—Show, Vienna, Austria.

April 13—Race meet, Brooklands track, Weybridge, England.

April 21—S. A. E. research division meeting, New York City.

April 22—Track races, Bakersfield, Cal.

May.

May 5—S. A. E. electrical equipment division meeting, New York City.

May 12—S. A. E. ball bearing division meeting, New York City.

May 14—S. A. E. motor testing division meeting, New York City.

May 25-26—Targa Florio race, Italy.

May 30—500-mile race, Indianapolis, Ind.

May 30—Track meet, New York City.

May 30—Track races, Providence, R. I.

June.

June 1—Coupe Florio race, Palermo, Italy.

CONDITIONS NOW NORMAL.

Excitement Over Ford Profit Sharing Plan Dies Away—Effect on Employees Noted.

Conditions in the vicinity of the Ford Motor Company's plant at Detroit have assumed their normal aspect. No longer thousands of men besiege the entrances on Manchester avenue in the hope of securing positions under the new wage regime. They have come to realize the futility of their campaign.

The painstaking manner in which the new wage scale was evolved and the thorough way in which the entire plan is being fortified by elaborate follow-up work is illustrated by several features. One of the most significant relates to the handling of employees in the shops to discover by a thorough test their fitness for work in the various departments and thus to protect them against a seeming failure to make good and a summary dismissal.

Foremen are not allowed to dismiss a man arbitrarily. If the head of the department finds a man is not doing satisfactory work, instead of dismissing him outright, he must send him to a clearing house, where his case is investigated and he is given another trial in some other department, unless he is found to be wholly inefficient. There his ability for another kind of work will be tested. These shifts may take place a half a dozen times before the man is dismissed.

The company is determined that the additional money received shall be devoted to reasonable purposes. In order to decide this a large number of investigators have been selected from the factory. They study the employees and ascertain how the money is utilized. If it be found that any employee is not profiting as he should by the additional money, he must prove that he can, or he no longer participates in the profit sharing plan.

"TIRE OBSERVATION".

Goodyear Tire & Rubber Company Issuing Series of Bulletins Dealing with Tires.

The Goodyear Tire & Rubber Company, the factory of which reached the production mark of 10,000 sets a day recently, is issuing a series of bulletins termed "Tire Observation". These deal with the various phases of the tire situation and are educational.

The information contained in the leaflets is not confined to any one subject, as inflation for

example, but explains how mileage may be increased and service of shoes prolonged. This is in keeping with the policy of the company to co-operate with users of its products.

ELECTRIC VEHICLE CONVENTION.

National Association to Hold Fifth Annual Event at Philadelphia in October.

The fifth annual convention of the Electric Vehicle Association of America will be held in Philadelphia during October. The exact dates have not as yet been made public. The Philadelphia section, organized during the present administration, and now numbering 50 members, is planning to make the 1914 event one of the most interesting and constructive that the association has ever held.

The papers to be presented this year will be unusually high grade and will treat extensively a large number of pertinent subjects. The titles and authors will be made known from time to time. An effort is being made to have all papers printed and available fully one month in advance of the convention so that sufficient time will be given for their proper study and consideration.

It will be interesting to note that at the time of the last convention held in Chicago, the association had 437 members, and sections in New England and Chicago, aside from the general office activities in New York. At this time the association has about 650 members, a gain of over 200 during five months, or at the rate of about 500 new members a year. It is expected that the 1000 mark will be attained by next October.

Pending the announcement of the convention committees, any and all communications regarding the Philadelphia convention should be addressed to the executive secretary, United Engineering Societies' building, 29 West 39th street, New York City.

OVERHAULING THE MOTOR CAR.

Attention is specially directed to the April 25 issue of The Automobile Journal, which will be the annual overhaul and equipment number. An effort will be made to present descriptions and illustrations of such equipment making for economy of time and labor. Manufacturers' data must be in the hands of the editor not later than April 18 to insure its publication.

Tarvia

*Preserves Roads
Prevents Dust -*

Boulevard, East Side Mississippi River, Minneapolis, Minn. Treated with Tarvia.

Automobile-Proof Highways

THE automobile has changed the problems of the road builder. What is required now is a form of construction which will not only give a good road surface the whole year round, but which will resist the abrasive action of automobile driving wheels. Tarvia furnishes the solution.

Tarvia is a dense, viscid coal tar product, resistant to weather, water and traffic. It has the property of sticking to cold stone and retaining its adhesiveness for many years.

It forms a matrix about the stone, making a Tarvia-concrete which is waterproof and automobile-proof. Being slightly viscid and plastic, it is not abraded by automobile driving wheels

but is simply rolled down. No dust is formed and no mud.

The cost of maintenance is so greatly reduced as to more than offset the cost of the Tarvia.

Suburban streets should be tarviated to secure a handsome, cleanly, mudless pavement at a low cost. Automobile thoroughfares and highways should be tarviated to keep down the maintenance expense. Park and cemetery roads should be tarviated to make them dustless and sightly. Boulevards should be tarviated because no other form of macadam will stand the traffic.

Booklets on request.

OFFER CASH PRIZES.**Emil Grossman Manufacturing Company to Give \$850 to Winning Drivers Using Its Product.**

The Emil Grossman Manufacturing Company, Inc., has decided to repeat its offer of cash prizes to contestants in the 500-mile Indianapolis race, and has authorized the officials to announce the following cash prizes, providing the drivers finishing in the first three places use Red Head spark plugs: To the driver finishing first, \$500; to the second, \$250, and to the third, \$100.

REMY SERVICE IN WAR.**El Paso, Tex., Expert Crosses Line into Mexico and Corrects Rebel Commander's Magneto.**

The following story is told as evidence of the service given its customers by the Remy Electric Company, Anderson, Ind., maker of the Remy magneto, etc.: General Caranza of the rebel forces in Mexico utilizes an Overland car and while at Juarez his operator experienced

trouble in starting. Despite repeated crankings and primings, the motor refused to respond. An onlooker informed the driver that the Remy company maintained a service station at El Paso, Tex., and the station was called on the 'phone. D. O. Cook, the resident expert, responded and within a few minutes after his arrival corrected the trouble, which proved to be a frayed wire.

DEALERS ORGANIZE.**Greensburg, Penn., Association to Hold Show in New Building on April 9-11.**

The motor car dealers of Greensburg, Penn., have organized and the new body has taken the name of the Westmoreland County Automobile Dealers' Association. The following are the officers: President, Charles Walters, Greensburg Auto Company; vice president, Gene Grey, Westmoreland Motor Car Company; secretary, William Van Horne, Greensburg Auto Company; treasurer, William Berlin, Patterson Berlin Auto Company.

The first annual show of the association will be held in the new Rose building, Greensburg, Penn., April 9 to 11 inclusive. The entire space of 208 by 105 feet will be filled with motor cars, cyclecars, motorcycles and accessories. The decorations will be very elaborate and music will be furnished by Wallace's Vocal Orchestra of Cleveland, O. The organization was effected through the efforts of L. J. Ward of Pittsburg, Penn., who will manage the show.

EQUIPPING THE GARAGE.

The purchaser of a new machine who intends to attend personally to its upkeep, will find many valuable suggestions dealing with the selection of the garage equipment in the annual overhaul and equipment number of The Automobile Journal of April 25.

The following concerns have been elected to membership in the Motor and Accessory Manufacturers: A. C. Smith, Milwaukee, Wis., axles, pressed steel hubs, etc.; Detroit Pressed Steel Company, Detroit, motor car frames and pressed steel parts; the Forbes Varnish Company, Cleveland, varnishes; the Van Sicklen Company, Aurora, Ill., speedometers; the English & Mersick Company, New Haven, Conn., automobile hardware, trimmings, lamps, etc.

Bosch Magneto

For Ford Cars

**More Power
More Speed
More Pleasure
More Economy**

A FORD engine is made remarkably powerful, speedy and economical by fitting a Bosch High Tension Magneto to replace the coil system regularly used.

By means of the Bosch-Ford Attachment the Bosch Magneto can be fitted in a few hours to any Ford Car—no coils, no complications, but an all-efficient, no-worry ignition system, the same as is now being used by the world's most prominent cars.

The Trade and Ford Owners can obtain instructive and convincing literature by writing for the Bosch-Ford Booklet, sent free on request.

\$5.00 Sent to Emory W. Clark, up in
Detroit makes you a Life Member of
THE ANTI-PIKERS ASSOCIATION OF AMERICA

One of these days you are going to get up, look the old boat over and say: "Well, wife, let's start for Market Street" or "Let's drive to Broadway."

Not a bit ridiculous!

When they get that **Lincoln Highway Finished** YOU CAN DO THAT VERY THING. It will be a joy to ride over it. You know how the pneumatics feel under you **ON YOUR OWN BOULEVARD**. That favorite boulevard in your own town has been worth **HUNDREDS OF DOLLARS** in **PERSONAL SATISFACTION**.

It's no pipe dream! It's a positive plan. It will be done!

Builders of motor cars and tire and other manufacturers have contributed millions. Cement makers have followed suit. Now we fellows with the cars should come across with our five spots or MORE.

We get in on the ground floor, but we get in **EASIER**. Europe can't touch a tour over this Highway from Broadway to Market Street, when it comes to **REAL NATURE THRILLS**, smooth going, wonderful scenery and **OZONE** that will put leather lungs in everybody.

THERE'S YOUR CHECK BOOK. You've got the manhood, the pen and the ink. **DO IT NOW!** They're waiting for you to sign. Pin this coupon to your check.

I am a regular motorist.

My name is.....

My address is.....

Herewith I contribute \$.....

Send me a contributor's certificate, membership card and radiator emblem.

Cartercar Company Pontiac Michigan

Why should the auto business be different from any other business? To my mind it is not, and the sooner it gets down to a horse sense basis the healthier it will be. The day when it was a "game" is gone. The red fire and hurrah period is past. And the companies which stay in are the ones which are going to adopt a hard-headed, close-margined, business-like policy.

**While Overhauling
Your Car Remem-
ber This.**

Dependable lubrication is not secured by flooding the finely finished bearings and gears of your cars with ordinary oil or grease. Where the life of your car and its efficient operation depends so largely upon the use of suitable lubricant, such haphazard methods are extremely dangerous. You should exercise as much care and judgment in selecting a lubricant as you would in selecting a car. If you abide by such methods your unvarying choice would be

TRADE MARK REGISTERED IN
NON-FLUID OIL
UNITED STATES PATENT OFFICE

This reliable and effective lubricant is indorsed by the majority of the leading auto manufacturers. Non-Fluid Oil produces a strong film between the bearing surfaces, which will not thin out under the action of frictional heat and allow them to come together. Non-Fluid Oil will not gum and harden in cold weather after the manner of ordinary grease. The frequent repairs and unexpected expenses due to the use of ordinary oils and greases are entirely eliminated when Non-Fluid Oil is employed. Efficiency and economy in motor car operation demands the use of this reliable lubricant. Non-Fluid Oil comes packed in only orange enamelled cans bearing the above trade mark. See that you get it.

BUYING AND SELLING MADE EASY

15,000 Trade Interests

READ THE
Accessory and Garage Journal
EACH MONTH

You can secure your monthly audience with all buying and selling heads in all concerns in every branch of the automobile industry through the Accessory and Garage Journal. Such interests must know what you have to offer. All are logical prospective purchasers. They constitute your market and are always looking for lines of merit.

In this magazine the large and small manufacturer has equal opportunity to reach the whole trade and can secure a service equal to that of a trade mailing list and better than can be secured through any other medium.

100 Per Cent. Quantity—100 Per Cent. Quality—Circulation Value.

Every order carries with it a positive guarantee of service stated, and this in any form requested.

Ask how we give concern and product listing under proper classification in Buyers' Guides that have a distribution of more than 1,100,000 copies yearly. This service is free. Our trade mailing list is 100 per cent. active—Do you need it? Details gladly furnished on request.

as easily as folding top.

SPRINGFIELD METAL BODY CO.

SPRINGFIELD

MASS.

There's no leak proof ring but the **LEAK-PROOF** Ring

Takes the Slant Out of Hills:

- ❑ It's the up-hill work that puts the power plant of your car to the real, honest efficiency test.
- ❑ The amount of push your pistons are able to deliver decides whether you get up smoothly and freely or fight for every foot. You want *all* the power your

engine was designed to produce if the slant is to be taken out of the hill.

- ❑ It's only a matter of power then—full power is a matter of perfect compression, and perfect compression depends largely on piston rings. Leaky piston rings rob you of power at every stroke. With

MADE IN
ALL SIZES

LEAK-PROOF Piston Rings

EASILY
ADJUSTED

gas leakage is impossible, perfect compression results and the maximum delivery of power is obtained.

- ❑ The opening found in all one-piece piston rings is closed in the **Leak-Proof Ring** because the two sections interlock, each one sealing the slot in the other. These sections are concentric, not eccentric, so constructed that equally distributed tension gives equally perfect bearing on the cylinder walls. They are stronger than any other form of piston ring, either one-piece or of more than two pieces, because of their construction on the angle-iron principle,—only possible in this two-piece type. This is an exclusive and patented feature of the **Leak-Proof Ring**.

They are made of Processed Gray Iron,—softer than the cylinder yet more lasting than the motor.

- ❑ **Leak-Proof Piston Rings** ensure a strong, steady, normal pulse to your engine when your car is climbing hills as well as on level ground. They take the slant out of hills.
- ❑ **The Difference**—They never lose their spring and elasticity through constant heating and cooling off.
- ❑ They reduce carbonization to a minimum by keeping built-up surplus oil.
- ❑ They are continuously efficient—easily adjustable.

Send For Our Booklet—It tells all about Leak-Proof Piston Rings. Why you need them on your engine. How they can save fuel and conserve power. Send for it. It is free and informative.

AUTOMOBILE JOURNAL

\$1.00 the year
10 cents the copy

PAWTUCKET R.I.

April 25, 1914

Teach your customers oil economy

Show them that the only way to get their money's worth of lubrication is to buy the best oil in the market. Then sell it to them—it's the quickest way to build up your oil business.

Manufacturers of all grades of cars agree that three-fourths of all engine troubles are due to faulty lubrication. There's money for you in selling *lubrication* instead of *oil*; in selling service and satisfaction.

Tell your customer that the most nearly perfect lubricant made will be by far the cheapest for him in the end. Tell him he will make no mistake if he uses

VEEDOL

*the oil which gives the most lubrication with
the least carbon deposit*

If your customer has been using an inferior oil, it's your chance to make a friend of him for life. Show him that the difference is probably not more than \$5 or \$10 a year and switch him over to VEEDOL—he'll thank you for it.

VEEDOL is a proven oil, refined from Pennsylvania petroleum. It is the result of our 30 years experience with lubricating oils. We know it is the best cylinder oil ever produced.

Write for details of our new selling plan, if there is no agent for VEEDOL in your vicinity. We want responsible representatives everywhere. Our intensive consumer advertising will make your name as well as the name of VEEDOL, familiar to every car owner in your vicinity.
